Hanson—Cox —On July 15th, at St Paul's, Knightsbridge Dr David C Hanson, to Norma Constance, daughter of Mr and Mrs John M Cox, of Derryhale, Dundalk, Ireland

DEATHS

Hugo —On July 17th, at Devonia House, Crediton, Devon (the residence of his sister), Edward Henry Hugo, M B, B S, of Berryfield, Bodmin, Cornwall, aged 44 years

Rose —On July 15th, at Norbury Lodge Upper Norwood, Anthony Strong Rose, L R C P, L R C S, L F P S

Steen —On July 12th, at Sutherland avenue, Bexhill on Sea Prof Robert Hunter Steen, M D, F R C P, late Medical Superintendent, City of London Mental Hospital, Dartford, aged 56

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

An Address

ON THE

MECHANISM OF PANCREATIC SECRETION.

Delivered at the Institute of Pathology and Medical Research, St. Mary's Hospital, London,

By JOHN MELLANBY, M.D. Camb.,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON

(*From the Sherrington School of Physiology, St. Thomas's Hospital, S.E.*)

A general survey of the activities of the body indicates that the functions of the liver and pancreas are intimately related to one another. In this lecture I propose to show how the external secretion of the liver (bile) determines the external secretion of the pancreas (pancreatic juice) I shall consider the subject from the following standpoints: (1) the presence of bile in the duodenum as the intestinal stimulus for pancreatic secretion; (2) secretin as the specific stimulus for the pancreas; (3) the relation of bile-salts to secretin—the isolation of secretin: (4) the path of absorption of secretin: (5) the influence of the vagus nerve on the composition of pancreatic juice: and (6) the mechanism for the discharge of bile into the duodenum

Presence of Bile in the Duodenum as the Intestinal Stimulus for Pancreatic Secretion.

From general considerations of structure it is evident that the rate of secretion of pancreatic juice should be comparable to that of saliva. In the early days of experimental physiology it was observed that a dog with a permanent pancreatic fistula gave a copious secretion of pancreatic juice after feeding. In acute experiments, however under general anæsthesia, it was difficult to obtain more than a few drops of pancreatic juice even after such procedures as vagal stimulation, the intravenous injection of pilocarpine, the injection of alcohol into the alimentary canal, &c. The first important information in regard to pancreatic secretion arose from the observation that the introduction of hydrochloric acid into the stomach or duodenum led to a secretion of pancreatic juice. This fact was investigated by many observers but in this lecture I propose to discuss two views only. In 1901 Popielski[1] stated that the introduction of hydrochloric acid into the duodenum caused the secretion of pancreatic juice by a local reflex nervous mechanism between the duodenum and pancreas. In 1902 Bayliss and Starling[2] showed that this conception was erroneous since the introduction of acid into the duodenum, isolated from the body except by its blood-vessels still caused a secretion of pancreatic juice. This result led directly to the experiment in which Bayliss and Starling gave a striking demonstration of hormone action—namely that an acid decoction of the duodenal mucosa injected into the blood stream produced a large secretion of pancreatic juice. These experiments formed the basis of the hypothesis which has been generally accepted for the past 20 years—that prosecretion exists in the mucous membrane of the duodenum, that hydrochloric acid from the stomach converts prosecretin into secretin, and that secretin after absorption into the blood is carried to the pancreas and excites it into activity.

It has long been recognised, however, that many facts militate against the acceptance of this hypothesis which makes pancreatic secretion dependent upon gastric secretion Thus Czerny[3] observed that a dog which had undergone complete gastrectomy lived and showed no diminished power of digestion. This animal experiment has its homologue in the many successful cases of more or less complete gastrectomy which have been carried out on human beings. Further, achlorhydria is a relatively common occurrence in apparently normal individuals and is not associated with any digestive disturbances. Finally, Dodds and Bennett[4] carried out a series of experiments on themselves in which they introduced a neutral food into the duodenum. A fall in the percentage of CO_2 in the alveolar air indicated that normal pancreatic secretion followed this duodenal alimentation. A consideration of all these facts led me to reinvestigate the mechanism of pancreatic secretion. At the outset I assumed the accuracy of the prosecretin hypothesis and made secretin extracts by boiling the duodenal mucosa with 0 2 per cent. HCl, &c

Distribution of Prosecretin.—Prosecretin varies widely in its distribution in animals. In the carnivorous animal (cat) it is practically limited to the duodenum; in the omnivorous animal (pig) it is found in considerable quantities at least 10 feet from the pyloric sphincter: in the herbivorous animal (goat) large quantities are found not only in the duodenum but also in the ileum. This distribution indicated that acids other than hydrochloric were capable of converting prosecretin into secretin. To test this hypothesis extracts were made of the duodenal mucous membrane with water containing amino-acids as glutamic acid, leucine, and tyrosine. All these extracts contained large quantities of secretin, although it may be observed that leucine and tyrosine are neutral to litmus (Mellanby and Huggett).[5]

Preparation of Secretin.—This result led me to explore systematically the conditions under which secretin solutions may be made. Extracts of the duodenal mucous membrane of a pig were made with a variety of solvents and the comparative secretin contents of these extracts were determined. The table of figures shows the number of drops of pancreatic juice secreted as the result of injecting 2 c.cm. of the following extracts into the femoral vein of a series of anæsthetised cats:—

Extract	Pancreatic juice (drops)	Extract.	Pancreatic juice. (drops)
75 % alcohol	28	H_2O	16
75 % acetone	24	0·05 % NaOH .	20
5 % NaCl .	24	0 1 % NaOH ..	12
0·7 % NaCl	20	0·2 % HCl	20

From these experiments it was evident that hydrochloric acid possesses no specific capacity for making secretin from prosecretin Latterly I[6] have shown that elevation of temperature is not essential. In fact, the best method for making secretin consists in grinding up the duodenal mucous membrane with four parts of absolute alcohol at room temperature. The filtrate contains a large quantity of secretin in a relatively stable condition since it shows no loss of activity even after considerable periods of time. These results prove conclusively that secretin exists in a preformed condition in the mucous membrane of the small intestine, the distribution of this secretin varying in different species of animals.

Specific Stimulus for Pancreatic Secretion.—Bayliss and Starling assumed that the formation of secretin from prosecretin by the action of acid chyme led ipso facto to the absorption of this secretion into the blood, and hence to the secretion of pancreatic juice. But if secretin exists in a preformed condition in the duodenal mucous membrane the problem arose as to what particular intestinal event (assuming that secretin calls out the activity of the pancreas) causes the absorption of secretin into the blood and hence to the discharge of pancreatic juice. In the literature on the subject of pancreatic secretion a large number of substances have been described as producing a flow of pancreatic juice when injected into various parts of the alimentary canal. Among such substances may be mentioned hydrochloric acid, water, fats soaps, alcohol mustard, and croton oil. A large number of experiments were carried out to investigate these

Epsom salts was given on some days in addition Twenty-eight of the patients were entirely free from colic or pain whilst using isacen Of the remaining 19, one had severe pain before and during defæcation, whilst 18 occasionally had some pain either before or during defæcation. The number of movements fluctuated from one to two, seldom three to four, daily Occasionally there was no movement for a day or two in some of the cases These results were obtained during one month's trial of the remedy and the patients included sufferers from chronic nephritis, severe chronic constipation, myocarditis, and pulmonary tuberculosis Dr Einhorn and Dr. Rafsky conclude by remarking that "a laxative remedy will certainly be more efficacious in healthy persons than in invalids Isacen has proved of great help in these old and helpless patients and will certainly be of assistance in the routine work of treating constipation" Such a conclusion based on clinical observation is more convincing than formulæ

THE WARNEFORD MENTAL HOSPITAL

THE centenary of the Warneford Mental Hospital, which was celebrated on July 15th, forms the occasion for the issue of a brief history of the hospital, which has been compiled for the committee of management A meeting of the governors of the Radcliffe Infirmary on April 28th, 1813, was the genesis of the hospital, though the expediency of erecting such an institution in the vicinity of Oxford had been previously discussed A sum of £20,000 was raised, and on July 10th, 1826, the hospital, then known as the Oxford Lunatic Asylum, was opened for the reception of patients "who, though poor, were not paupers, those who, though above poverty, were far from affluence, and those who, though blessed with a sufficiency to meet the ordinary calls on their resources, were unable to satisfy the pressing demands of a heavy calamity" Dr James Adey Ogle, Aldrich Professor of Medicine, was the first (non-resident) medical superintendent, in 1828 the first resident medical officer was appointed in the person of Mr F T Wintle, and the name of the institution was changed to the Radcliffe Asylum, in appreciation of the large sums of money contributed by the Radcliffe Trustees In 1843, in order to make some enduring record of the generous benefactions of Dr Samuel Wilson Warneford, whose donations over a period of 42 years exceeded the value of £70,000, it was resolved again to change the name of the institution, which became known as the Warneford Asylum, later incorporated as the Warneford Lunatic Asylum At the present time the hospital, which began on 10 acres and accommodated 30 patients, now has an estate of 120 acres and provides beds for 130 patients It is at the present time a registered hospital for the care and treatment of both sexes of the upper and middle classes when suffering from nervous and mental disorders Though it has not been possible of recent years to treat so many patients at reduced fees as in times past, those who cannot afford to pay full fees are not refused, and the committee of management invite donations to increase the funds at their disposal for this purpose

PROFESSIONAL STANDARDS

To the Editor of THE LANCET

SIR,—I was called in to attend a patient who had a blood pressure of 235, on the strength of which I prevailed upon him to stay in bed for two or three days. On calling on the fourth day I found his blood pressure was 220 He is an active-minded and energetic man, with very definite ideas of his own, and feels that if he pays, he can go where he likes On the following day, when I arrived at his house, his blood pressure was 210, and after I had taken it, he informed me that he had been so alarmed at the advice I had given him, about keeping still and quiet, resting in bed and milk diet, that when I had left his house on my last visit he got straight out of bed, dressed himself, and went round to another doctor, A, to whom he explained the whole situation

Dr A thereupon, at his request, took his blood pressure and found it was only 160 My patient put it to me afterwards thus "I have every confidence in you doctors, but I have no confidence in your machine" This opened my eyes to the possibility of a mechanical error in my sphygmomanometer I was so disturbed at my patient's behaviour, and Dr A's action, even to the extent of informing my patient that he would stand by his pressure-reading in a court of law, that I thereupon suggested a second opinion of my own choosing I brought on the following day a specialist of high repute, who examined the patient thoroughly, noting his general condition and took his blood pressure, this was 225, and the consultant gave the patient sound advice about resting in bed until his pressure had absolutely gone down and stabilised itself

Before the consultant left I took the opportunity of showing to the patient a certificate which I had received from the maker of my blood-pressure machine that very day, when I had taken it to be tested, and it proved to be absolutely accurate against the standard column at their works The next day I took the patient's blood pressure again, and it was 220 On the following day, on my arrival at the house, there were present not only another doctor, Dr B, but a specialist brought by him with the full knowledge that this man was under my care I learned who this second specialist was, and I know who Dr B is who brought him, also I happen to know who the Dr A was

It was interesting to learn that the second consultation resulted in agreement with what the specialist brought by me said, and with all that I had personally told my patient from the start

Have standards of professional conduct changed?

I am, Sir, yours faithfully,

July 14th, 1926 HONORIUS.

DIPHTHERIA IMMUNISATION

To the Editor of THE LANCET.

SIR,—A tragedy we hear of from time to time—the loss of an only child from diphtheria—must cause regret to those of our profession who are interested in diphtheria immunisation Very few parents are aware that they can have their children immunised against this serious disease I am sure many medical officers of health would be pleased to learn from their colleagues in general practice how they think this knowledge can best be brought home to parents

I am, Sir, yours faithfully,

C W HUTT

Holborn Town Hall, July 16th, 1926

THE MEDICAL KING'S PRIZEMAN

A CORRESPONDENT draws our attention to the fine performance of Dr F. H Kelly as a rifle shot in tying for the King's Prize at Bisley. He writes :—"I may say without fear of contradiction that Dr Kelly, with the possible exception of Arthur Fulton, also a winner, has for some years been the finest all-round rifle shot in Great Britain. This distinction is all the more remarkable in that he does no rifle-shooting during the year other than at the annual Bisley meeting Dr Kelly was third in the competition last year, another medical man, Dr C W Wirgman being second, while another, Dr C H Vernon, was tenth Dr Kelly in recent years has won at Bisley the Grand Aggregate in 1914, 1922 and 1923, the All-comers Aggregate in 1922 and 1923, the Service Rifle Championship in 1914, and the Elkington Aggregate in 1923 and 1925 In the King's Prize he has previously reached the final stage in 1920, 21, 22, 23, and 25, winning the Bronze Medal in the first stage in 1922 In 1924 he was again in a leading position in the aggregates but was unable to remain at Bisley for the latter part of the meeting"

We agree with our correspondent that this is a very remarkable record of skill and consistency

THE REBUILDING OF ST BARTHOLOMEW'S HOSPITAL IN THE EIGHTEENTH CENTURY

Now that that venerable house of mercy, St Bartholomew's Hospital, is about to undergo a scheme of reconstruction, a paper appearing in the current volume of the Hospital Reports, by Sir D'Arcy Power, on the reconstruction begun in 1730 and finished in 1769, has a special interest Of the buildings of the pre-Reformation Hospital practically nothing is known, but in the year 1617 a plan was made which is still extant and was reproduced in the second volume of Norman Moore's "History of the Hospital" This plan shows that most of the site of the hospital now occupied by buildings for medical or surgical use was then covered with houses In 1680 the hospital began to be enlarged, and by 1712 a committee decided that three new wards should be built, which came into use about 1714 In 1730 the "first pile decided upon by the Committee of 1723 was begun, James Gibbs being architect and the builder the well-known Ralph Allen, of Prior Park, Bath, who supplied the stone from his own quarries" The foreman in charge of the work was Richard Biggs, and, showing that present-day difficulties in the building trade are not new, we find Mr Allen writing that "Allabaster's people, who are setting the stone, are abusive and very idle The carpenters too are very dilatory in laying the floors" The "first pile" consisted of the present Great Hall, with its staircase ornamented by the Hogarth paintings and the Treasurer's House By 1736 a second pile was ordered—i e, the present south wing, and in 1743 a third pile was begun, the present west wing Then came the war of the Austrian succession, which held up the building until 1749, when building recommenced The block was finished and came into use about 1752 With this date the first portion of Sir D'Arcy Power's paper ends.

An Address

ON THE

MECHANISM OF PANCREATIC SECRETION.

Delivered at the Institute of Pathology and Medical Research St Mary's Hospital, London,

BY JOHN MELLANBY, M.D. CAMB.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON

(From the Sherrington School of Physiology, St. Thomas's Hospital, S.E.)

A GENERAL survey of the activities of the body indicates that the functions of the liver and pancreas are intimately related to one another. In this lecture I propose to show how the external secretion of the liver (bile) determines the external secretion of the pancreas (pancreatic juice) I shall consider the subject from the following standpoints: (1) the presence of bile in the duodenum as the intestinal stimulus for pancreatic secretion. (2) secretin as the specific stimulus for the pancreas: (3) the relation of bile-salts to secretin—the isolation of secretin; (4) the path of absorption of secretin: (5) the influence of the vagus nerve on the composition of pancreatic juice; and (6) the mechanism for the discharge of bile into the duodenum

PRESENCE OF BILE IN THE DUODENUM AS THE INTESTINAL STIMULUS FOR PANCREATIC SECRETION

From general considerations of structure it is evident that the rate of secretion of pancreatic juice should be comparable to that of saliva In the early days of experimental physiology it was observed that a dog with a permanent pancreatic fistula gave a copious secretion of pancreatic juice after feeding. In acute experiments however under general anæsthesia it was difficult to obtain more than a few drops of pancreatic juice even after such procedures as vagal stimulation, the intravenous injection of pilocarpine the injection of alcohol into the alimentary canal, &c. The first important information in regard to pancreatic secretion arose from the observation that the introduction of hydrochloric acid into the stomach or duodenum led to a secretion of pancreatic juice. This fact was investigated by many observers but in this lecture I propose to discuss two views only In 1901 Popielski [1] stated that the introduction of hydrochloric acid into the duodenum caused the secretion of pancreatic juice by a local reflex nervous mechanism between the duodenum and pancreas In 1902 Bayliss and Starling [2] showed that this conception was erroneous since the introduction of acid into the duodenum isolated from the body except by its blood-vessels, still caused a secretion of pancreatic juice. This result led directly to the experiment in which Bayliss and Starling gave a striking demonstration of hormone action—namely that an acid decoction of the duodenal mucosa injected into the blood stream produced a large secretion of pancreatic juice. These experiments formed the basis of the hypothesis which has been generally accepted for the past 20 years—that prosecretion exists in the mucous membrane of the duodenum that hydrochloric acid from the stomach converts prosecretin into secretin and that secretin after absorption into the blood is carried to the pancreas and excites it into activity

It has long been recognised, however, that many facts militate against the acceptance of this hypothesis which makes pancreatic secretion dependent upon gastric secretion Thus Czerny [3] observed that a dog which had undergone complete gastrectomy lived and showed no diminished power of digestion This animal experiment has its homologue in the many successful cases of more or less complete gastrectomy which have been carried out on human beings. Further, achlorhydria is a relatively common occurrence in apparently normal individuals and is not associated with any digestive disturbances Finally, Dodds and Bennett [4] carried out a series of experiments on themselves in which they introduced a neutral food into the duodenum A fall in the percentage of CO_2 in the alveolar air indicated that normal pancreatic secretion followed this duodenal alimentation. A consideration of all these facts led me to reinvestigate the mechanism of pancreatic secretion At the outset I assumed the accuracy of the prosecretin hypothesis and made secretin extracts by boiling the duodenal mucosa with 0·2 per cent. HCl, &c.

Distribution of Prosecretin.—Prosecretin varies widely in its distribution in animals. In the carnivorous animal (cat) it is practically limited to the duodenum; in the omnivorous animal (pig) it is found in considerable quantities at least 10 feet from the pyloric sphincter; in the herbivorous animal (goat) large quantities are found not only in the duodenum but also in the ileum This distribution indicated that acids other than hydrochloric were capable of converting prosecretin into secretin To test this hypothesis extracts were made of the duodenal mucous membrane with water containing amino-acids as glutamic acid leucine, and tyrosine. All these extracts contained large quantities of secretin, although it may be observed that leucine and tyrosine are neutral to litmus (Mellanby and Huggett) [5]

Preparation of Secretin.—This result led me to explore systematically the conditions under which secretin solutions may be made. Extracts of the duodenal mucous membrane of a pig were made with a variety of solvents and the comparative secretin contents of these extracts were determined. The table of figures shows the number of drops of pancreatic juice secreted as the result of injecting 2 c.cm of the following extracts into the femoral vein of a series of anæsthetised cats —

Extract	Pancreatic juice (drops)	Extract	Pancreatic juice (drops)
75 % alcohol	28	H_2O . .	16
75 % acetone	24	0·05 % NaOH	20
5 % NaCl	24	0·1 % NaOH . .	12
0·7 % NaCl .	20	0·2 % HCl . .	20

From these experiments it was evident that hydrochloric acid possesses no specific capacity for making secretin from prosecretin Latterly I [6] have shown that elevation of temperature is not essential. In fact the best method for making secretin consists in grinding up the duodenal mucous membrane with four parts of absolute alcohol at room temperature. The filtrate contains a large quantity of secretin in a relatively stable condition since it shows no loss of activity even after considerable periods of time. These results prove conclusively that secretin exists in a preformed condition in the mucous membrane of the small intestine the distribution of this secretin varying in different species of animals.

Specific Stimulus for Pancreatic Secretion [7]—Bayliss and Starling assumed that the formation of secretin from prosecretin by the action of acid chyme led ipso facto to the absorption of this secretion into the blood and hence to the secretion of pancreatic juice. But if secretin exists in a preformed condition in the duodenal mucous membrane the problem arose as to what particular intestinal event (assuming that secretin calls out the activity of the pancreas) causes the absorption of secretin into the blood and hence to the discharge of pancreatic juice. In the literature on the subject of pancreatic secretion a large number of substances have been described as producing a flow of pancreatic juice when injected into various parts of the alimentary canal. Among such substances may be mentioned hydrochloric acid, water, fats soaps alcohol, mustard, and croton oil A large number of experiments were carried out to investigate these

Epsom salts was given on some days in addition Twenty-eight of the patients were entirely free from colic or pain whilst using isacen Of the remaining 19, one had severe pain before and during defæcation, whilst 18 occasionally had some pain either before or during defæcation The number of movements fluctuated from one to two, seldom three to four, daily Occasionally there was no movement for a day or two in some of the cases These results were obtained during one month's trial of the remedy and the patients included sufferers from chronic nephritis, severe chronic constipation, myocarditis, and pulmonary tuberculosis Dr Einhorn and Dr Rafsky conclude by remarking that "a laxative remedy will certainly be more efficacious in healthy persons than in invalids Isacen has proved of great help in these old and helpless patients and will certainly be of assistance in the routine work of treating constipation" Such a conclusion based on clinical observation is more convincing than formulæ

THE WARNEFORD MENTAL HOSPITAL

THE centenary of the Warneford Mental Hospital, which was celebrated on July 15th, forms the occasion for the issue of a brief history of the hospital, which has been compiled for the committee of management A meeting of the governors of the Radcliffe Infirmary on April 28th, 1813, was the genesis of the hospital, though the expediency of erecting such an institution in the vicinity of Oxford had been previously discussed A sum of £20,000 was raised, and on July 10th, 1826, the hospital, then known as the Oxford Lunatic Asylum, was opened for the reception of patients "who, though poor, were not paupers, those who, though above poverty, were far from affluence, and those who, though blessed with a sufficiency to meet the ordinary calls on their resources, were unable to satisfy the pressing demands of a heavy calamity." Dr James Adey Ogle, Aldrich Professor of Medicine, was the first (non-resident) medical superintendent, in 1828 the first resident medical officer was appointed in the person of Mr F T Wintle, and the name of the institution was changed to the Radcliffe Asylum, in appreciation of the large sums of money contributed by the Radcliffe Trustees In 1843, in order to make some enduring record of the generous benefactions of Dr Samuel Wilson Warneford, whose donations over a period of 42 years exceeded the value of £70,000, it was resolved again to change the name of the institution, which became known as the Warneford Lunatic Asylum, later incorporated as the Warneford Lunatic Asylum At the present time the hospital, which began on 10 acres and accommodated 30 patients, now has an estate of 120 acres and provides beds for 130 patients It is at the present time a registered hospital for the care and treatment of both sexes of the upper and middle classes when suffering from nervous and mental disorders Though it has not been possible of recent years to treat so many patients at reduced fees as in times past, those who cannot afford to pay full fees are not refused, and the committee of management invite donations to increase the funds at their disposal for this purpose

An Address

ON THE

MECHANISM OF PANCREATIC SECRETION.

Delivered at the Institute of Pathology and Medical Research, St. Mary's Hospital, London,

BY JOHN MELLANBY, M.D. CAMB.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON

(From the Sherrington School of Physiology, St. Thomas's Hospital, S.E.)

A GENERAL survey of the activities of the body indicates that the functions of the liver and pancreas are intimately related to one another In this lecture I propose to show how the external secretion of the liver (bile) determines the external secretion of the pancreas (pancreatic juice) I shall consider the subject from the following standpoints: (1) the presence of bile in the duodenum as the intestinal stimulus for pancreatic secretion: (2) secretin as the specific stimulus for the pancreas: (3) the relation of bile-salts to secretin—the isolation of secretin; (4) the path of absorption of secretin; (5) the influence of the vagus nerve on the composition of pancreatic juice; and (6) the mechanism for the discharge of bile into the duodenum

PRESENCE OF BILE IN THE DUODENUM AS THE INTESTINAL STIMULUS FOR PANCREATIC SECRETION.

From general considerations of structure it is evident that the rate of secretion of pancreatic juice should be comparable to that of saliva. In the early days of experimental physiology it was observed that a dog with a permanent pancreatic fistula gave a copious secretion of pancreatic juice after feeding. In acute experiments however under general anæsthesia, it was difficult to obtain more than a few drops of pancreatic juice even after such procedures as vagal stimulation, the intravenous injection of pilocarpine the injection of alcohol into the alimentary canal, &c. The first important information in regard to pancreatic secretion arose from the observation that the introduction of hydrochloric acid into the stomach or duodenum led to a secretion of pancreatic juice. This fact was investigated by many observers but in this lecture I propose to discuss two views only In 1901 Popielski[1] stated that the introduction of hydrochloric acid into the duodenum caused the secretion of pancreatic juice by a local reflex nervous mechanism between the duodenum and pancreas In 1902 Bayliss and Starling[2] showed that this conception was erroneous since the introduction of acid into the duodenum isolated from the body except by its blood-vessels, still caused a secretion of pancreatic juice. This result led directly to the experiment in which Bayliss and Starling gave a striking demonstration of hormone action—namely that an acid decoction of the duodenal mucosa injected into the blood stream produced a large secretion of pancreatic juice. These experiments formed the basis of the hypothesis which has been generally accepted for the past 20 years—that prosecretion exists in the mucous membrane of the duodenum that hydrochloric acid from the stomach converts prosecretin into secretin and that secretin after absorption into the blood is carried to the pancreas and excites it into activity

It has long been recognised however, that many facts militate against the acceptance of this hypothesis which makes pancreatic secretion dependent upon gastric secretion Thus Czerny[3] observed that a dog which had undergone complete gastrectomy lived and showed no diminished power of digestion This animal experiment has its homologue in the many successful cases of more or less complete gastrectomy which have been carried out on human beings. Further, achlorhydria is a relatively common occurrence in apparently normal individuals and is not associated with any digestive disturbances Finally, Dodds and Bennett[4] carried out a series of experiments on themselves in which they introduced a neutral food into the duodenum A fall in the percentage of CO_2 in the alveolar air indicated that normal pancreatic secretion followed this duodenal alimentation A consideration of all these facts led me to reinvestigate the mechanism of pancreatic secretion At the outset I assumed the accuracy of the prosecretin hypothesis and made secretin extracts by boiling the duodenal mucosa with 0 2 per cent HCl, &c

Distribution of Prosecretin.—Prosecretin varies widely in its distribution in animals. In the carnivorous animal (cat) it is practically limited to the duodenum; in the omnivorous animal (pig) it is found in considerable quantities at least 10 feet from the pyloric sphincter; in the herbivorous animal (goat) large quantities are found not only in the duodenum but also in the ileum This distribution indicated that acids other than hydrochloric were capable of converting prosecretin into secretin To test this hypothesis extracts were made of the duodenal mucous membrane with water containing amino-acids as glutamic acid, leucine, and tyrosine All these extracts contained large quantities of secretin although it may be observed that leucine and tyrosine are neutral to litmus (Mellanby and Huggett)[5]

Preparation of Secretin.—This result led me to explore systematically the conditions under which secretin solutions may be made. Extracts of the duodenal mucous membrane of a pig were made with a variety of solvents and the comparative secretin contents of these extracts were determined The table of figures shows the number of drops of pancreatic juice secreted as the result of injecting 2 c.cm of the following extracts into the femoral vein of a series of anæsthetised cats.—

Extract	Pancreatic juice (drops)	Extract.	Pancreatic juice. (drops)
75 % alcohol .	28	H_2O .	16
75 % acetone	24	0·05 % NaOH .	20
5 % NaCl .	24	0 1 % NaOH .	12
0 7 % NaCl	20	0 2 % HCl . ..	20

From these experiments it was evident that hydrochloric acid possesses no specific capacity for making secretin from prosecretin Latterly I[6] have shown that elevation of temperature is not essential. In fact, the best method for making secretin consists in grinding up the duodenal mucous membrane with four parts of absolute alcohol at room temperature. The filtrate contains a large quantity of secretin in a relatively stable condition since it shows no loss of activity even after considerable periods of time These results prove conclusively that secretin exists in a preformed condition in the mucous membrane of the small intestine, the distribution of this secretin varying in different species of animals

Specific Stimulus for Pancreatic Secretion.—Bayliss and Starling assumed that the formation of secretin from prosecretin by the action of acid chyme led ipso facto to the absorption of this secretion into the blood, and hence to the secretion of pancreatic juice. But if secretin exists in a preformed condition in the duodenal mucous membrane the problem arose as to what particular intestinal event (assuming that secretin calls out the activity of the pancreas) causes the absorption of secretin into the blood and hence to the discharge of pancreatic juice. In the literature on the subject of pancreatic secretion a large number of substances have been described as producing a flow of pancreatic juice when injected into various parts of the alimentary canal. Among such substances may be mentioned hydrochloric acid, water fats soaps, alcohol, mustard, and croton oil A large number of experiments were carried out to investigate these statements On one occasion only a definite secretion of pancreatic juice was obtained—namely, after the injection of 50 c cm of 0 1 per cent HCl into the duodenum of a cat In this case only 10 drops of juice were secreted in 30 minutes It was evident, therefore that the entrance of hydrochloric acid into the duodenum does not constitute the essential stimulus for pancreatic secretion The clue to the solution of the problem was obtained from an experiment in which extracts of various portions of the alimentary canal, alone or in conjunction with one another, were injected into the duodenum of a cat It was found that the injection of a mixture of bile and an acid extract of the pyloric mucous membrane was followed by a copious secretion of pancreatic juice After a latent period of ten minutes pancreatic juice was secreted at the rate of two drops a minute, and the secretion continued for two hours At the end of that time 6 c cm of pancreatic juice had been collected

Dilute Bile into the Duodenum—An analysis of this result showed that the effect was due to the introduction of dilute bile into the duodenum, the addition of the acid extract of the pyloric mucous membrane having conferred on the bile the adequate reaction for calling out its activity. The following experimental results illustrate the essential facts

10 c cm of dilute acidified bile (2 c cm bile, 8 c cm 0 9 per cent NaCl 0 05 c cm HCl N) was injected into the duodenum of a fed cat After a short latent period (five minutes) pancreatic juice was rapidly secreted, thus —

Minutes	Pancreatic juice (drops)	Minutes	Pancreatic juice (drops)
5	1	24	40
7	5	36	60
9	10	65	80
13	20	95	100

An analysis of this result showed that the essential factor was the cholic acid contained in the bile-salts, since the injection of pure sodium cholate of an adequate reaction into the duodenum led to a large secretion of pancreatic juice

Function of Mucin in Bile—The injection of bile-salts or bile-acids into the gut often led to hæmolysis and hæmoglobinuria This fact suggested a possible function for mucin Therefore the comparative activities of bile (A) and mucin-free bile (B) as pancreatic excitants were determined

Pancreatic juice (drops)	A		B	
	Hrs	Mins	Hrs	Mins
1	0	54	0	22
5	0	58	0	29
10	1	16	0	34
20	1	21	0	47
40	1	32	0	57
90	2	20	1	5
120	2	53	—	—

The result indicates that mucin delays the absorption of bile-salts and thereby prevents hæmolysis of the red cells of blood whilst prolonging the action on the pancreas

The Adequate Reaction of Bile—I have stated that bile injected into the duodenum should possess an adequate reaction in order to cause a secretion of pancreatic juice During this investigation it was observed that the injection of bile, which had been rendered slightly acid, into the duodenum in the majority of cases caused a copious secretion of pancreatic juice In a few cases, however, practically no juice was secreted A detailed investigation into this fact showed that the state of alimentary activity of the animal exercised a great influence on the capacity of any given bile to evoke a secretion of pancreatic juice Briefly stated, a recently fed cat (within four hours of feeding) gave a large secretion of pancreatic juice after the injection of slightly acidified bile (pH 6 5) into the duodenum, if, however, the cat had not been fed for 24 hours the effective pancreatic stimulant was the injection of a slightly alkaline bile (pH 8 0) into the duodenum. This fact illustrates the influence of reaction on the activities of the alimentary canal

SECRETIN AS THE CAUSE OF PANCREATIC ACTIVITY

I have shown that bile injected into the duodenum calls out a secretion of pancreatic juice, and that the active substance in the bile is cholic acid I now propose to consider the question whether the immediate agent stimulating the pancreas to activity is cholic acid, or secretin, or some hitherto undescribed substance The direct injection of cholic acid into the blood causes no secretion of pancreatic juice Therefore cholic acid is not the immediate stimulant to the pancreas On the other hand the injection of cholic acid into the duodenum calls out a secretion of pancreatic juice, whereas a similar injection into the ileum evokes no pancreatic response In both cases the solution of cholic acid appears to be absorbed The essential difference between the duodenum and ileum in the cat is that the former contains preformed secretin in the mucosa whilst the latter contains no secretin It appears, therefore, that the absorption of cholic acid from the duodenum carries the secretin contained in the cells of the mucous membrane into the blood and thence to the pancreas, and that the immediate pancreatic stimulus is secretin carried to the pancreas by cholic acid This assumption receives substantial support from experiments in which the vagus and sympathetic nerves were paralysed by atropine and ergotamine respectively

Paralysis of Vagus by Atropine—It is a well known fact that paralysis of the vagus by atropine does not diminish, but slightly increases, the quantity of pancreatic juice secreted after the intravenous injection of secretin into an animal The following experiment shows that vagal paralysis gives similar results on pancreatic secretion after the injection of dilute bile into the duodenum

Pancreatic juice (drops)	A		B	
	Mins	Secs	Mins	Secs
1	9	40	0	20
10	9	30	6	35
20	13	35	11	54
40	24	22	20	0
60	36	40	28	12

Secretion A was obtained after the injection of 10 c cm dilute bile (pH 6 5) into the duodenum After the cessation of this secretion 10 mg of atropine were injected into the cat Complete paralysis of the vagus ensued Table B shows the rate of pancreatic secretion subsequently produced by the injection of bile similar to that used in experiment A The figures show an augmentation of secretion similar to that observed after the direct injection of secretin into the blood

Paralysis of the Motor Side of the Sympathetic by Ergotamine—Paralysis of the sympathetic by the intravenous injection of ergotamine (1 mg) does not diminish the pancreatic activity of secretin injected directly into the blood Similarly, ergotamine does not diminish the capacity of bile injected into the duodenum to cause a secretion of pancreatic juice The inability of vagal and sympathetic paralysis to influence the efficacy of an injection of bile into the duodenum to stimulate the pancreas affords strong evidence in favour of the assumption that the immediate stimulus to pancreatic activity is the presence of secretin in the blood

RELATION OF SECRETIN TO BILE-SALTS—THE ISOLATION OF SECRETIN

It is evident from the foregoing statements that the presence of bile of an adequate reaction in the small intestine causes secretin to pass from the cells of the mucosa into the blood and hence leads to a secretion of pancreatic juice The probable mechanism of this secretion is indicated by the method I have described for the isolation of secretin This method is based on three observations: (*a*) secretin exists in a preformed condition in the duodenal mucosa: (*b*) secretin may be extracted from the mucous membrane by absolute alcohol; and (*c*) secretin is adsorbed from solution by precipitated bile-acids. A preliminary account of this method has been published In this lecture I wish to emphasise the fact that the addition of bile-salts to the extract of 0.2 per cent. to an acid solution of secretin results in the precipitation of bile-acids to which the whole of the secretin is adsorbed This observation probably indicates the essential mechanism whereby the introduction of bile-salts into the duodenum causes a secretion of pancreatic juice—viz. the bile-salts in their passage through the intestinal mucosa adsorb the secretin contained in the cells, and thereby carry it into the blood, and so to the pancreas. Secretin isolated by bile-salt precipitation possesses a remarkable degree of activity. since 0.03 mg. evokes the secretion of 3 c.cm of pancreatic juice in a cat It is freely soluble in water and a strong solution gives a faint biuret reaction and a definite Pauly reaction Since Millon's test is negative the positive Pauly reaction probably indicates that secretin contains histidine or some derivative of it in its molecule It is very rapidly destroyed by pepsin and trypsin Heating to 100° C with NaOH (0.1 M) for five minutes destroys it: similar heating with HCl (0.1 M) destroys 50 per cent of it. These properties indicate that secretin is a polypeptide Purified secretin exercises no depressant action on the blood pressure. Incidentally it may be observed that although secretin possesses properties very similar to those of insulin, yet a subcutaneous injection of secretin has no effect on the blood-sugar of a rabbit, although such an injection causes a slow flow of pancreatic juice. Therefore its action is limited to the external secretion of the pancreas, and it has no effect on carbohydrate metabolism either directly or indirectly through an action on the islets of Langerhans

The Path of Absorption of Secretin [8]

In 1917 Djenab[9] stated that secretin injected into the portal circulation is a much less effective stimulant of pancreatic secretion than when injected into the jugular vein. This observation has been confirmed by many observers (Halliburton and de Souza[10] Cowgill and Deuel[11]) Since the obvious path of absorption of secretin is via the portal blood these results indicated that secretin is not necessary for the production of pancreatic juice in the normal animal. The experimental results described by Djenab are invariably obtained when crude secretin solutions are injected in turn into the femoral and mesenteric veins The diminished secretion in the latter case is very striking Thus in one experiment the injection of 2 c.cm of secretin into the femoral vein of a cat resulted in the production of 25 drops of pancreatic juice whilst a similar injection into the mesenteric vein caused the secretion of only 10 drops of juice. It is evident that this apparently anomalous action of secretin may be due to one of two causes: (*a*) the initial action of secretin on the liver. or (*b*) the absorption of secretin from the intestinal mucosa into the lacteals and its indirect passage into the blood

Bayliss and Starling in their original paper. stated that secretin in addition to stimulating the pancreas to activity doubles the rate of flow of bile. It appeared. therefore that an injection of secretin into the portal circulation would result in the secretin acting as a cholagogue rather than as a stimulant of pancreatic secretion This hypothesis was tested by determining the relative capacities of secretin to act as a cholagogue when injected into the femoral vein and into the portal vein It was found that the hypothesis was incorrect since secretin was a less effective stimulant to the liver when injected into the portal vein than when injected into the femoral vein As an alternative hypothesis it was assumed that secretin was absorbed into the lacteals from the intestinal mucosa and passed indirectly into the blood through the left thoracic duct This hypothesis appeared to be supported by the well-known observation that a meal of fat promotes the secretion of a large quantity of pancreatic juice in a dog with a pancreatic fistula This hypothesis also was tried by direct experiment. In this case the efficacy of bile injected into the duodenum to cause a secretion of pancreatic juice before and after tying the left thoracic duct was determined. It was found that the ligature of the thoracic duct neither increased nor diminished the secretion of pancreatic juice produced after the injection of dilute bile into the duodenum No evidence was therefore obtained that secretion or any other alimentary stimulant to pancreatic secretion was absorbed into the lymphatic system of the intestine. The correct explanation of Djenab's striking results was obtained from the comparative effects on pancreatic secretion produced by the injection of pure secretin into the portal and the femoral vein respectively. This experiment showed that there is practically no difference in the amount of pancreatic juice secreted after the injection of pure secretin into the portal or the femoral blood. Thus 0.05 mg. of secretin contained in 1 c.cm of 0.9 per cent. NaCl was injected in turn into the femoral vein and a small branch of the mesenteric vein of a cat In the former case the total secretion amounted to 60 drops in the latter case to 50 drops of pancreatic juice Probably the anomalous results obtained when crude secretin extracts are injected into the two circulations are due to the association of the secretin in such extracts with other substances which are removed from the portal blood when passing through the liver. The results may illustrate the importance of the liver in protecting the body against the absorption of poisons from the alimentary canal—a liver function which has been emphasised by Willcox[12] and designated by the word toxiphylactic.

Influence of the Vagus Nerve on the Composition of Pancreatic Juice [13]

I have previously confined myself to the consideration of the humoral control of pancreatic secretion. In this section I propose to consider the part played by the nervous system in the mechanism

Previous to the discovery of secretin the nervous mechanism was supposed to play the dominant rôle in pancreatic secretion But whereas in acute experiments on dogs under general anæsthesia injections of secretin may produce 150 c.cm of pancreatic juice in the course of a few hours stimulation of the vagus nerves either by electrical methods or by the intravenous injection of small doses of pilocarpine rarely produces 10 c.cm of pancreatic juice in a similar time. Further, it was shown that the quantity of pancreatic juice secreted as the result of the intravenous injection of secretin was independent of the paralysis of the vagus by atropine On the basis of these results it was assumed generally that secretin played the dominant rôle in pancreatic secretion and that the vagus took only a minor part in the mechanism. and possibly only came into action as the immediate result of taking food Two facts however. militated against this hypothesis. (*a*) the extraordinary concentration of enzymes contained in vagal pancreatic juice, and (*b*) clinical observations on cases of dyspepsia. A detailed examination of the quantity and quality of pancreatic juice under a variety of conditions established the important function of the vagus nerve in pancreatic secretin

The composition of seven successive quantities of pancreatic juice secreted by a cat under the influence of secretin was determined The following figures show the quantities of sodium bicarbonate. trypsinogen, and amylase in these fractions:—

Per cent of $NaHCO_3$ (N)—						
0.125	0.124	0.134	0.128	0.132	0.128	0.124
Units of trypsinogen—						
665	640	360	400	230	260	130
Units of amylase—						
340	290	160	100	70	70	60

Two facts are evident from these figures: (*a*) throughout the experiment the quantity of

$NaHCO_3$ contained in the successive portions of juice remained approximately constant about a mean value of 0·128 N *per cent*; and (*b*) the quantities of trypsinogen and amylase continually decreased during secretion, the final fraction containing less than one-quarter of trypsinogen and one-sixth of amylase of the quantities in the first fraction.

This result might have been due to the exhaustion of the fluid under the secretin stimulus. This hypothesis, however, does not accord with the histological appearance of the gland at the end of a long period of activity produced by secretin Moreover, it is directly negatived by the effect of vagal stimulation (by the intravenous injection of pilocarpine) after the apparent exhaustion of the gland by the action of secretin

The following figures show this effect of vagal stimulation —

Secretin only					Secretin containing 2 mg pilocarpine
Per cent of $NaHCO_3$ (N)—					
0 150	0 158	0 156	0 148	0 146	0 146
Units of trypsinogen—					
1350	1300	1150	800	600	1300
Units of amylase—					
270	210	160	160	60	200

The figures show the constancy of the bicarbonate and the steady diminution in trypsinogen and amylase in successive fractions of the pancreatic juice secreted under the stimulus of secretin only, but after the injection of pilocarpine—i e, after the stimulation of the vagal endings in the gland—the quantity of alkali remained the same, but the trypsin and amylase contents of the juice were raised to approximately their initial concentration These and a series of similar experiments illustrate the relative functions of secretin and the vagus nerves in the mechanism of pancreatic secretion Briefly stated, it seems that the metabolism of the enzymes of the pancreas is under the control of the vagus nerves, whilst the quantity of fluid and the bicarbonate content of this fluid is determined by secretin

Secretin, therefore, determines the presence in the intestine of the pancreatic enzymes in a large volume of sodium bicarbonate solution. This solution possesses an optimum reaction for the activity of lipase, amylase, and trypsin, and is able to preserve the neutrality of the intestinal contents during digestion This dual hypothesis coordinates the views of Pavlov and his fellow workers on the function of the vagus in pancreatic digestion with the work of Bayliss and Starling on the humoral control of pancreatic secretion

Discharge of Bile into the Duodenum

I propose to deal in a brief way only with this subject The majority of animals possess a gall-bladder which acts as a reservoir for the storage of bile during the quiescent periods of digestion A few animals, such as the horse and rat, possess no gall-bladder, but in these animals the biliary passages are dilated so as to form a comparatively large reservoir for bile It is evident, therefore, that the discharge of bile into the duodenum must be considered from two points of view (*a*) the relaxation of the common bile-duct leading into the duodenum, (*b*) the contraction of the gall-bladder

(*a*) The mechanism of this reaction has been variously stated to be under the control of the vagus and sympathetic system of nerves, and also to be due to a local reflex from the intestine to the gall-bladder It appears, however, that the mechanism is more simple There is no doubt but that the passage of a peristaltic wave of contraction from the pylorus greatly diminishes for a few seconds the pressure required to force fluid from the common bile duct through the ampulla of Vater into the duodenum This effect is doubtless due to the obliquity of the entrance of the common bile-duct into the duodenum, and to the fact that the peristaltic wave of contraction is always preceded by a definite wave of relaxation This wave of *relaxation* practically annuls the contraction of the sphincter around the entrance of the bile-duct into the duodenum

(*b*) As a subsidiary factor, however, the contraction of the gall-bladder must be considered In a fasting animal the gall-bladder is always distended with bile, in a recently fed animal the gall bladder is practically empty despite the fact that the natural flow of bile is directly into the gall-bladder If strips of gall bladder are suspended in warm oxygenated Ringer a well-marked contraction is produced by adding a trace of pure secretin to the fluid It appears, therefore, that secretin absorbed into the blood not only stimulates the pancreas to secrete, but also contracts down the gall-bladder, and thereby ensures the discharge of bile into the duodenum when a peristaltic wave of contraction passes from the pyloric sphincter down the small intestine

General Considerations

As a result of the observations detailed in this lecture the following may indicate the sequence of events in the normal animal which lead to the orderly secretion of pancreatic juice During the period of alimentary rest the liver continuously secretes bile which is stored in the gall-bladder After eating, usually within 20 minutes, peristaltic waves of contraction pass down the intestine from the pyloric sphincter of the stomach During the passage of these waves the intestinal muscle surrounding the entrance of the common bile-duct into the duodenum is relaxed Bile therefore is forced from the distended gall-bladder into the duodenum This bile is mixed with the contents from the stomach, which gives it an adequate reaction to ensure the absorption of bile-salts through the intestinal mucosa

The bile-salts in their passage through the cells adsorb the preformed secretin contained in them and pass into the portal blood The secretin causes the pancreas to secrete and the liberated bile salt is carried to the liver to cause the secretion of a further quantity of bile In addition the secretin in the portal blood causes the gall-bladder to pass into a state of tonic contraction, so that as it empties the pressure is kept up to ensure the direct discharge of secreted bile into the duodenum The cessation of pancreatic secretion occurs therefore when bile is no longer discharged into the duodenum—i e, when peristaltic waves of contraction cease to be initiated at the pyloric sphincter—and this probably occurs after the emptying of the stomach of food The mechanism admirably illustrates the interdependence of the activities of the pancreas and liver, and correlates the digestive functions of the former with the metabolic activities of the latter

THE EFFECTS OF FEEDING ANTERIOR LOBE PITUITARY EXTRACT TO CHILDREN.

By H. GARDINER-HILL, M.B. CAMB., M.R.C.P. LOND.,
AND
J. FOREST SMITH, M.R.C.P. LOND.

(*From the Clinical Medical Unit, St. Thomas's Hospital.*)

THIS paper is a preliminary report on the effects of feeding anterior lobe pituitary extracts to children. The observations have extended over a period of one year. It has frequently been held that such preparations when given by the mouth, are entirely inert but the extracts we have used appear to influence both growth and metabolism, and in the former connexion at any rate corroborate the experimental work on amphibians, and more recent work on other animals.

In dealing with children, however, there are a number of factors one cannot control. In connexion with growth particularly it is impossible to say what the course of events might have been had treatment not been undertaken. The age at which different children begin to grow varies considerably and the liability of even the most under-developed to sudden spurts is well recognised In the cases mentioned in the present paper, however, the condition before treatment appears to have been either stationary or steadily deteriorating and there were in all cases associated disturbances of metabolism which have also been improved by treatment.

Type of Case Investigated.

The cases we have investigated fall into three groups—first, children with infantilism and defective growth: secondly, older female children with minor degrees of this condition and disturbances of menstruation: and thirdly, children with obesity of the apparently endogenous type.

In the first group, where the main features are infantilism and defective growth, anterior lobe feeding appears to have produced a stimulation of growth and bone development and an improvement in carbohydrate metabolism

In the second group where the main features are poor development with irregular and scanty menstruation, also associated with defective carbohydrate metabolism, anterior lobe feeding appears to have brought about an increase in the frequency and quantity of the menstrual losses with a similar improvement in metabolism No instance has been noted, however of the onset of menstruation occurring as a result of treatment in girls of this type with primary amenorrhœa.

In the third group, where the main feature is obesity of the endogenous type we have not been able to observe any noticeable diminution of weight as a result of anterior lobe feeding This is contrary to the usual statements There does however, appear to have been an improvement in carbohydrate metabolism as a result of treatment. The patients seem generally to have gained rather than lost weight. In females of this group a beneficial effect on menstruation has been noted. and this is probably a point worth taking into consideration, when the tendency of these children to periods of amenorrhœa is remembered

It is obvious, of course that in none of the groups that we have mentioned can a positive diagnosis of pituitary disturbance be made in the present state of our knowledge In the absence of a tumour of the gland, there is no known means of making this diagnosis In none of the cases of the present series was there any evidence of a pituitary tumour and if there had been, little benefit could have been expected from anterior lobe treatment. On the other hand, the clinical features, the disturbances of growth and bone development, of genital function and carbohydrate metabolism, which are presented in these children, bear such a striking resemblance to those seen in pituitary disease, that one is tempted to explain them on a pituitary basis. There can be no absolute justification for this and none is offered It is suggested only that these children are not normal from the point of view of development or function, and that the course of events can probably be modified to some extent and benefit derived from the administration of anterior lobe pituitary extract.

Functions of Anterior Lobe of Pituitary

Before going into the question of our results, brief reference may be made to the most recent experimental work in animals, both ablation and feeding experiments, as they throw additional light on the functions of this part of the gland Paulesco,[1] Cushing,[2] Aschner,[3] and others showed originally that partial removal of the anterior lobe in animals leads to obesity, genital hypoplasia, and lack of development of the skeleton with undergrowth Since then other observers have repeated these experiments. and although there is general agreement as to the lack of growth and genital hypoplasia, there has been some difference of opinion as to whether the operation is followed by obesity. Bell[4] did not find it, although in his experience it did follow the operations of compression and separation of the stalk. Recently Dott[5] has carried out a series of experiments in dogs, and also made a thorough review of the literature of this subject. Taking all the evidence into consideration he concludes that a syndrome—namely, depression of temperature, lethargy, obesity, retardation of growth and degenerative changes in the thyroid and genital glands—results from partial removal of the anterior lobe, or injury to its blood-supply, or from equivalent experiments Dott and Fraser,[6] in a report to the Medical Research Council, have also shown that partial removal of the anterior lobe leads to disturbances of bone development. There is a decrease in epiphyseal activity with degeneration of cartilage and diminution of activity at the ossifying junction They also found that by feeding their animals with anterior lobe extracts, an increase of epiphyseal activity with intense ossification at the epiphyseal junction took place Radiological studies confirmed these observations. The effect of anterior lobe feeding on the general state of the animal was to accelerate growth and development. They suggest, however, that anterior lobe feeding does not produce gigantism, for though the animals grow faster and mature earlier, their epiphyses ossify sooner and the normal limits of stature are not exceeded Positive results with anterior lobe feeding experiments have been reported by previous observers, notably Schafer,[7] Goetsch[8] and Marinus.[9]

A considerable amount of work has also been done on the relationship between the thyroid gland and the anterior lobe of the pituitary, chiefly by Loeb[10] Biedl,[11] and recently by Dott The latter found in his animal experiments that partial removal of the anterior lobe was followed by a thyroid hyperplasia of some seven days' duration with subsequent involutionary changes and hypoplasia. Anterior lobe feeding however, produced no obvious changes in the thyroid histology. In another series of animals after thyroidectomy there was a hyperplasia of the anterior lobe of the pituitary to double the normal size In this series no obvious changes in the pituitary body followed thyroid feeding

As to the experimental work on the relationship between the anterior lobe of the pituitary and the genital glands various observers, notably Paulesco Cushing Aschner and Dott, have shown that partial removal of the anterior lobe in young animals leads to a syndrome of infantilism. The animals remain infantile in size, configuration behaviour, and sexuality. The secondary sexual characteristics fail to develop Dott has reported atrophy of the testicles following this operation, and in the female animals functional disturbances of the generative organs, as the failure to come on heat At post-mortem the uterus and tubes were found to be smaller than even the infantile size of the animal would warrant Histologically, the ovaries showed definite degenerative changes As a result of anterior lobe feeding, on the other hand, he found an acceleration of ovarian development, the follicles being much larger than in the control animals Sexual function was also established at an earlier date

From this brief review of the experimental work in connexion with the anterior lobe, it seems fairly reasonable to conclude that it is intimately connected at any rate with growth and genital function, leaving the question of obesity still for the present sub judice, also that, following its partial removal, degenerative changes occur in the thyroid and genital glands It also seems clear that feeding experiments with anterior lobe extracts in animals give positive results on growth and bone development From the results of treatment with these extracts in children, we are hoping to show that similar results can sometimes be expected

GROUP 1 —*Effect of Anterior Lobe Feeding in Infantilism.*

As illustrations of the first group of cases of children with infantilism, lack of development, and defective growth, details of two infantile boys, both 12 years of age, who have been treated with anterior lobe pituitary extract with considerable benefit and acceleration of growth are given.

1. F V., aged 12 This boy was sent to hospital for lack of growth This was first noticed at the age of 8, and since then his mother had kept accurate measurements of his height from time to time Between the ages of 8 and 11 he grew at the rate of 1 inch (roughly 2½ cm) per annum, but during the following year (11 to 12), the year before he came under treatment, his rate of growth fell to half an inch (1 25 cm) per annum This, of course, is considerably below the average rate of about 5 cm per annum for a boy of this age

When he was first examined by us he appeared to be a miniature of the so-called hypopituitary type of individual, rather plump, very under grown and under-developed, but mentally alert He formed a most striking contrast to his brother, who was only three years older but 2 feet taller and 4 st heavier, and from the secondary sexual characteristics point of view most remarkably developed for a boy of 15. His mother was a small woman, his father of average build The boy had apparently been always remarkably free from illness and there was no history or evidence of any of the usual complaints with which infantilism is generally associated His height was 106 cm The average for a boy of this age is about 140 cm He was longer in the trunk than in the limbs, the symphysis vertex measurement being 54 5 cm , symphysis soles 50 5 The sella turcica was about average size The visual fields were normal His bone development was considerably delayed, being that of a child of 7 The centre for the semilunar bone of the wrist should normally appear at the age of 5 In this boy the centre had not yet appeared in the left wrist, and was only just appearing in the right, when he was first brought to hospital at the age of 12

Pituitary treatment was started in October, 1924 He has been given desiccated anterior lobe extract (Armour) by the mouth in gradually increasing doses, and for the second six months of treatment has been taking 15 gr a day In the course of a year he has grown 7 25 cm as against 1 25 in the previous year He has had no other treatment His bone development has advanced to a corresponding extent. X ray photographs taken at intervals of about three months give a good idea of this There are now very well-developed centres for the semilunar bones in each wrist, and the centre for the pisiform is also present This does not appear normally until the twelfth year The bones are still, of course, below average size, but as far as the appearance of epiphysial centres goes, bone development is now reported on as " about normal " During the year he has also gained steadily in weight. When he first came to hospital he weighed 3 st 1 lb At the end of his year's treatment his weight had increased to 3 st 8½ lb , a gain of 7½ lb —about 17 per cent of his original weight

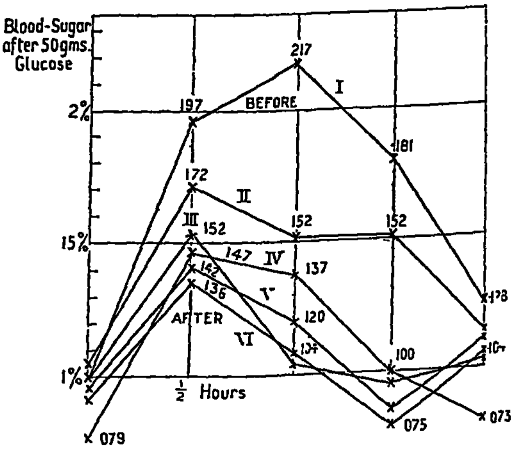
There has also been a considerable improvement in his carbohydrate metabolism as judged by the results of carbohydrate-tolerance tests (obtained by estimating the blood-sugar at half-hourly intervals after 50 g of glucose) The whole question of the improvement of the carbohydrate metabolism after anterior lobe feeding is dealt with later in this paper But in this case, as in the others, a preliminary decreased tolerance which we have regarded as a sign of inability to deal with sugar has become increased after treatment to a level above the normal

This case has been recorded in some detail as the results have been so striking, and it is difficult to explain them except on the assumption that the anterior lobe extracts are active and have influenced metabolism Previously the boy's condition was apparently steadily deteriorating, and there was no reason to suppose that any spontaneous improvement was on the point of taking place This possibility however, must not be entirely overlooked

We have at the present moment a number of these infantile children under treatment with anterior lobe extract, but the majority were only started a few months ago, when we found that our trials were proving fruitful It is early yet to make any definite statements as to increase in growth and bone development, but the carbohydrate metabolism appears to be following the course already described One other infantile boy, however, was put on this treatment a year ago, after a period of observation and treatment for ten months with cod-liver oil. The result has been the same

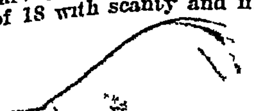
C C , aged 12 This boy's height when he started treatment was 118 cm , the average for a boy of his age being 140 cm His weight was 3 st 10 lb , as against the average for age of 5 st 6 lb He was far below average in development, though his mentality was alert. His bone development was delayed, but to nothing like the same extent as in the first case mentioned His sella turcica was about normal for a boy of his size. His Wassermann reaction was negative , his sugar tolerance considerably decreased Treatment with anterior lobe pituitary extract was commenced in November, 1924 The dose was gradually increased to 15 gr a day In the course of a year he has grown 6 cm , a rate which is slightly in excess of the average for his age During the previous ten months, whilst he was under observation and on cod-liver oil, he only grew 3 cm. The rate of growth has been almost doubled His bone development has advanced but is still behind the normal, the centre for the pisiform bone not having yet appeared His weight has increased to 4 st 7 lb since starting anterior lobe pituitary treatment This is a gain of 8 lb in the year During the previous year he only gained 2 lb Sugar-tolerance estimations show the same improvement which was noted in the first case The actual curves before and after treatment are demonstrated in Chart 1 Again, it is difficult to account for the improvement, except on the assumption that the extracts are active

CHART 1



GROUP 2 —*Effect of Anterior Lobe Feeding in Undeveloped Girls with Menstrual Disturbance*

As illustrations of the second group of cases of older female children with lack of development and menstrual disturbance, we would like to mention two examples, who derived benefit from anterior lobe treatment They represent different grades of severity of the same condition The first is an undeveloped girl of 19 with primary amenorrhœa The second an undeveloped girl of 18 with scanty and irregular



menstruation. In the first, the more advanced case menstruation has *not* commenced in spite of anterior lobe treatment for five months, although there has been a very definite improvement in metabolism. This has been our experience in other cases of this type, where puberty is considerably delayed. Anterior lobe extract does not appear to be effective in inducing menstruation under these circumstances. One supposes that the atrophic condition of the pelvic organs has become too far advanced. But in other ways these girls are markedly under-developed and poorly nourished. Their bone development is behind the average; their ability to utilise sugar, as judged by the results of sugar-tolerance tests, defective. And it is from the metabolic aspect that we have noticed improvement as a result of anterior lobe treatment. The details of this case are as follows:—

D. H., aged 19. This girl was sent for examination because menstruation had not yet started. Pelvic examination in the gynæcological department showed that the uterus was of the infantile type and extremely small. Her height was only 146 cm., her weight only 5 st. 8 lb. She is said to have stopped growing at the age of 10. Her bone development was considerably delayed, the epiphyses being still widely open. Her mentality was infantile. In addition to her menstrual trouble she also suffered from periodic frontal headaches which were accompanied by epistaxis. Her carbohydrate tolerance was markedly decreased. She has been treated on anterior lobe pituitary extract for five months with a considerable improvement in her general condition and metabolism. She has grown 2¾ cm. in that time—that is, at the rate of 5½ cm. per annum—growth previously being at a standstill for nine years. Her menstruation, however, has not started, though the periodic headaches with epistaxis have entirely ceased since the onset of treatment. Her weight has remained stationary. Improvement was shown in her sugar-tolerance curves.

The second case in this group illustrates the very considerable improvement in menstruation which results from anterior lobe treatment in the less advanced cases of this type. In these girls, after a normal or somewhat delayed onset, the menstrual losses tend to get more and more irregular and are finally followed by periods of amenorrhœa. These patients are also to some extent underdeveloped and poorly nourished. Their bone development is delayed and their ability to utilise sugar defective. As a result of anterior lobe pituitary treatment, the quantity and normal rhythm of the menstrual losses can to a large extent be re-established. This is accompanied by a similar improvement in metabolism.

The details of this second case are as follows:—

D. D., aged 18. Infantile type with poor development, started menstruating at the age of 13½, but the losses have always been irregular and scanty, occurring at intervals of from nine weeks to nine months. Immediately preceding treatment they had occurred at eight-weekly intervals on the last four occasions. Menstruation had always been accompanied by severe frontal headaches which were becoming steadily worse. On the last four occasions they had been of the migrainous type and accompanied by vomiting. She commenced treatment with anterior lobe pituitary extract and the dose was gradually worked up from 1 gr. three times a day to 5 gr. three times a day. She menstruated four times in the four succeeding months—on Nov. 12th, Dec. 15th, Jan. 18th, and Feb. 20th. The first period was accompanied by a characteristic headache with sickness, the second by a headache only, the last two were entirely free. She gained 5 lb. in weight in the four months. Her carbohydrate tolerance test, which in the first place showed a considerable decrease, at this stage gave a normal result.

GROUP 3.—*Effect of Anterior Lobe Pituitary Extract in Adolescent Obesity.*

In our experience there appear to be three main types of obese children. First, the type described by Frohlich[12] in which obesity is associated with lack of growth, delayed bone development, and genital hypoplasia. A pituitary tumour is sometimes present in these cases, though in others the disturbance seems to be one of pituitary function only. Secondly, a type in which the onset of obesity is accompanied by a period of accelerated growth and advanced development of bone and genital function which is well up to the average or even in excess of it. We have suggested elsewhere[13] that in these cases there is a preliminary period of over-activity of the anterior lobe. They do not ultimately become giants, because their epiphyses fuse early and growth ceases soon after puberty. Thirdly, a type in which obesity is accompanied by bodily development of the eunuchoid type and genital hypoplasia. The epiphyses remain open far longer than in the normal person and the obesity tends to diminish to some extent as growth advances. These patients often become taller than the average and continue growing beyond the average age.

The two cases described in this paper belong to the second type of adolescent obesity. On theoretical grounds, of course, it would be in the first type (provided the disturbance was one of function only) that benefit might be expected from this treatment. Unfortunately, we have not met with a case of this type recently and others have been treated with thyroid in addition to anterior lobe pituitary extract, as the latter does not reduce their obesity. The results consequently are of no value from the present standpoint. The giving of anterior pituitary to these two cases resulted in the same effect on the carbohydrate metabolism that we have previously described, but this method of treatment is not effective in reducing their obesity.

The first case in this group, S. E., aged 9, is a boy of average height and development, who had been gaining weight for about six months. When first seen, he was about a stone above the average in weight for his height and age. His sella turcica was small, his carbohydrate tolerance considerably decreased. For the past ten months he had suffered from fits of an epileptiform nature, occurring at intervals of from one to seven weeks. He was treated with anterior lobe pituitary extract, 1 gr. three times a day for a period of nine weeks, during which time he gained 9 lb. in weight. His fits occurred about once a week during this time. His carbohydrate metabolism, however, altered in a characteristic way, a previously low tolerance being considerably increased.

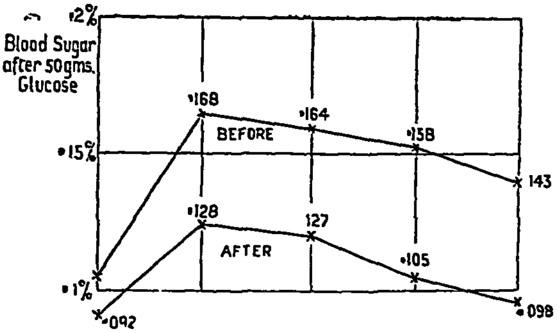
The second boy, D. L., aged 15, had developed obesity at the age of 10. The onset was sudden and accompanied by headaches. Previously he had been thin. When he was first brought to hospital he weighed 15 st. 2 lb., was above the average in height, and well developed. There was no evidence of pituitary tumour. His sella turcica was small, his visual fields and fundi normal. His bones were large, though the epiphyses were still unjoined, and at about the average stage of development. He was treated with anterior lobe pituitary extract, 15 gr. a day, for a period of two and a half months, and during this time he gained 9 lb. in weight. The sugar-tolerance curves, before and after treatment, show an increased tolerance still further increased.

Effect on Carbohydrate Metabolism.

The sugar-tolerance curves have been worked out according to MacLean's[14] method. The fasting blood-sugar was first determined, 50 g. of glucose given, and subsequent blood-sugar examinations carried out at half-hourly intervals for two hours. In the normal person the blood-sugar rises from a fasting level of about 0.1 per cent. to 0.17 per cent. or thereabouts at the end of half an hour; after this it falls to the normal level again at the end of an hour and a half. In the cases described in this paper the result has been different, the fall in the blood-sugar curve being gradual and delayed, and only reaching a level of about 0.14 to 0.15 per cent. at the end of two hours. It is assumed by the majority of investigators that the fall in the blood-sugar content is caused by the intervention of a storage mechanism, and that the oxidation of the ingested glucose is only a small factor. On this assumption the delayed curves seen in our cases would be considered to be the result of a defect in storage and represent a loss of power of the body to store sugar. This may or may not be so. We are hoping to obtain further information on this point from simultaneous examinations of the sugar tolerance and respiratory quotient. At the moment, however, our main object is to demonstrate that the sugar-tolerance curves of our patients alter very considerably as a result of treatment with anterior lobe pituitary extract and apparently alter consistently in the same direction The curves after treatment are all low and suggest an increase of carbohydrate tolerance, that is, they appear to represent an increased ability on the part of the body to store a single dose of 50 g of glucose. As a large majority of the patients gained weight on this treatment, there would appear to be some support for this view.

This general reduction in the blood-sugar readings following the administration of anterior lobe pituitary extract by mouth is represented in the chart by a composite curve obtained by averaging the results observed in nine cases before treatment compared with similar results in the same cases after treatment (Chart 2)

CHART 2



Composite curve embodying the nine cases

Type of Case Suitable for Anterior Lobe Treatment

Apart from clinical considerations, which come first in importance in deciding whether a child is a suitable case for the use of anterior lobe pituitary extract, we would like to lay stress on the defective carbohydrate metabolism which we have found present in these children Investigations of the sugar tolerance are of value both from the point of view of diagnosis and from that of control of treatment

It is advisable to make X ray examinations of the bone development Our usual routine is to examine the epiphyses of the lower end of the forearm and hand Where the bone development is delayed some improvement may be expected from treatment In actual practice, however, it is frequently found that some of the older children who are sent to hospital for defective growth have passed through a stage of accelerated growth with premature fusion of the epiphyses Under these circumstances, of course, the possibility of further growth is out of the question

Conclusions

1. Feeding of anterior lobe pituitary extracts by mouth does appear to have some therapeutic value, although the number of cases which we are quoting is too small to allow of dogmatic statements 2 In cases of infantilism, where the epiphyses are not already fused, these extracts appear of value in influencing growth 3 They may prove of value in certain types of amenorrhœa associated with minor degrees of infantilism 4 The effect of these extracts on the blood-sugar curve has been constant in all the cases which we have investigated, but in the present state of our knowledge we cannot attempt to give an explanation of this

SECONDARY JEJUNAL ULCERS

AND THEIR RADIOLOGICAL DIAGNOSIS

BY S GILBERT SCOTT, M R.C S, L R C P. LOND,
D M R E CAMB,
RADIOLOGIST AT THE LONDON HOSPITAL

PRIMARY jejunal ulcers, that is those ulcers which form primarily in the jejunum, not secondarily as the result of a gastro-enterostomy, are extremely rare, and a few only have been recorded. These, therefore, will not be considered

Secondary jejunal ulcers, however, are a serious drawback to the otherwise valuable operation of gastro-enterostomy, or, more correctly, jejunostomy, for gastric ulcer That they are a comparatively frequent complication cannot be denied Most authorities agree that in the majority of cases their occurrence is the combined result of trauma and infection, but this does not explain satisfactorily why the jejunum is more susceptible to trauma and infection after operation The acid gastric juices passing directly into the jejunum must, of course, play an important part in exaggerating a slight trauma. Unabsorbed sutures around the stoma are known to be one of the causes of ulceration, but this condition will not account for ulcers occurring well away from the site of operation

Joekes, by means of the duodenal drainage tube, has definitely established the fact that the normal contents of the jejunum in the human being are, if anything, slightly alkaline, but certainly not acid. Thus it would appear that damage to the lining mucous membrane of the jejunum is more than likely to occur when the very acid contents come in direct contact with it Its structure is not acid-resisting as is that of the stomach It seems, therefore, that the post-operative procedure of giving alkalines is sound, but it is doubtful whether this treatment achieves its object in all cases The duodenal drainage-tube might be used to investigate this point

There is another possible contributory cause However carefully a patient may be fed while under observation, the time comes when he is left to himself, and may find dieting very irksome; even if he does not have an occasional " bust," it is more than likely he will eat unsuitable food, and this will probably be imperfectly masticated

In the majority of cases examined radiologically, food is seen to pass almost directly through the stoma, the stomach, therefore, has but little opportunity of fulfilling its function as a digestive organ, consequently the jejunum and small intestine are at a great disadvantage, having to deal with food that has undergone little or no gastric digestion Thus it is surprising that the jejunal mucous membrane does not more often resent this ill-usage No doubt, with time, the jejunum can adjust itself to the new conditions and eventually become acid-resisting

The Rôle of Faulty Mastication.

Faulty mastication of food, due to many causes, including carelessness and hasty eating, is, I believe, the primary cause of 90 per cent of gastric ulcers

> " A man eats and walks
> As fast as his thoughts ! "

It needs but a small abrasion of the mucous membrane to form an ulcer, while a septic mouth, of course, renders the chances of bacterial invasion more probable As with the skin, an unbroken surface can

withstand infection while a pinprick may be sufficient to cause death

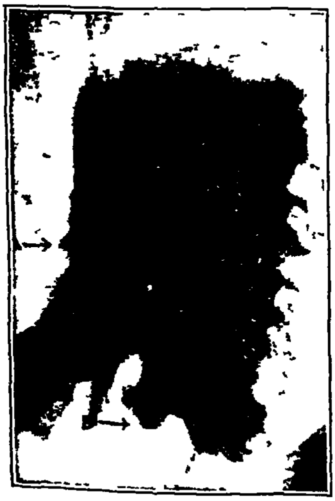
This theory, however, does not hold in those cases where foreign bodies get imprisoned in the stomach I have examined a mentally deficient patient who had over twenty articles in her stomach, including a meat hook, gas burner, keys, &c , yet at operation for their removal no ulceration of the mucous membrane could be detected. In the radiographic examination of the urinary tract I have found a sixpence that had been swallowed unknowingly in a Christmas pudding, some six months previously, yet the patient had no gastric symptoms whatever.

The Detection of Jejunal Ulceration.

The radiologist, in the course of his gastric work, examines many cases where symptoms point to ulceration of the jejunum after gastro-enterostomy, but such ulceration is probably seldom detected Personally, up to a few years ago, I had to content myself with merely reporting on the functioning powers of the stoma and with the examination of the stomach and duodenum, direct evidence of a jejunal ulcer was seldom obtained This was owing to faulty technique ; the large majority of these ulcers can now be accurately located.

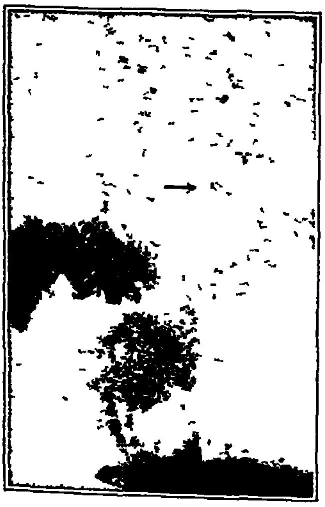
The method employed is based on the same principles as those used for gastric work—i e , systematic radioscopic palpation, details of which are given in the *Archives*, 1923, and in THE LANCET, 1922 Radioscopic palpation to most radiographers merely means prodding the abdomen after a full opaque meal This has probably been done since the early days of gastric radiology, but will certainly not give the same degree of accuracy in diagnosis as the method about to be described when efficiently practised and developed , it takes time and perseverance to become proficient in the art of palpation

FIG 2



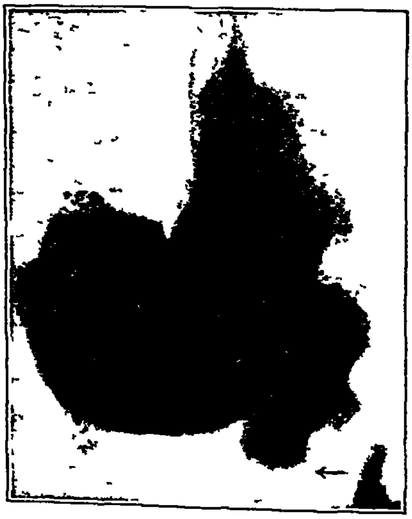
Gastric ulcer (A) and large jejunal ulcer (B)

FIG 3



Jejunal ulcer

FIG 4



Large jejunal ulcer

The main features of the method are as follows ·

(*a*) A meal of a creamy consistency is used I concocted, some years ago, a suitable barium cream for this purpose (now sold under the name of " Ramul ")

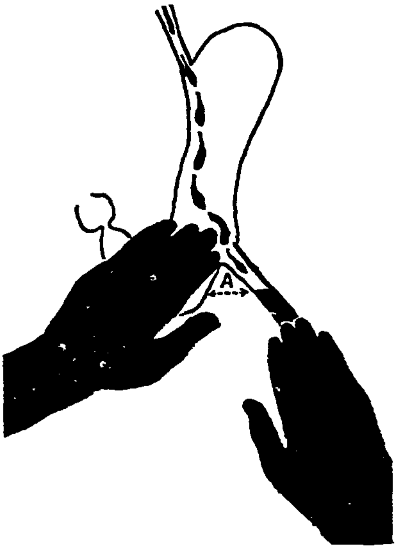
(*b*) Only a small quantity (3 oz.) of this is administered at first, This is important, as a full meal, say of from 6 to 7 oz., will defeat one s object

(*c*) By means of pressure of the hands on the abdomen, the opaque substance comes under full control

(*d*) It is then possible to smear the cream over each section of the mucous membrane systematically I have described this as " whitewashing " the interior of the stomach.

(*e*) The systematic examination of the *whole* stomach and duodenum must be emphasised—that is, the whitewashing process must start at the cardiac end, working down inch by inch and ending at the jejunum.

FIG 1.



Method of palpation, gastro jejunal angle (A)

Full control over the meal by this method takes some time to acquire At first much unnecessary energy is expended as many beginners will admit As in golf, where muscle alone will not send the ba as far as a well-timed swing, so with palpation, swing or knack is required to extract the full diagnostic value from the method

When a case of suspected jejunal ulcer after gastro-enterostomy is being examined, certain modifications of this technique are required The process is as follows —

The patient is instructed to swallow one mouthful only of the opaque cream. This is watched passing down the œsophagus into the cardiac end of the stomach It is then taken in charge by the palpating hands on the abdomen · and being controlled by this means, the emulsion can be carefully manœuvred through the stoma. The business of the left hand is now to prevent, by gentle pressure, any of the meal passing further into the body of the stomach, for, if the pylorus is passed, shadows in the afferent limb of the jejunum will cause confusion The business of the right hand is to dam up the emulsion in the first few inches of the efferent limb This manœuvre is not always easy to accomplish The opaque cream is now manipulated backwards and forwards through the stoma into the jejunum, and back again into the stomach This whitewashing process will cause the opaque substance to adhere to any ulcer crater present, showing itself as a black fleck or spot which remains isolated after the displacement of the contents by pressure This fleck, as in gastric ulcer, shows denser than the surrounding meal The penetrating type of ulcer is more usual and is easier to detect, as a nipple or bud-like projection on the jejunal wall This will also remain filled after displacement of the contents Pressure of the right hand is now released, allowing the contents to flow on into the remainder of the jejunum Six inches from the stoma may be considered the limit of jejunal ulceration The remainder of the meal is now swallowed and the rest of the stomach examined as a matter of routine

Ulcers may occur around the anastomosis or several inches from it in the efferent loop, usually just opposite the stoma itself These may be multiple, and are seldom found on the afferent side I have found that the majority of jejunal ulcers detected radiologically are in the angle formed by the greater curvature of the stomach and the efferent limb of the jejunum, (the gastro-jejunal angle, Fig 1, A) The closer the ulcer is to the anastomosis (gastro-jejunal ulcer), the deeper it will lie in this angle The true jejunal ulcer, usually of the penetrating type, is found as a rule projecting from the *inner* surface of the jejunum, well out of the gastro-jejunal angle Deep pressure in this angle will in many cases help to demonstrate an ulcer.

Those unaccustomed to this examination will at first experience difficulty in detecting an ulcer among the numerous projections and isolated flecks that will be seen in the neighbourhood simulating ulcers, and the inexperienced are more apt to see ulcers that are not there than to miss the genuine lesion The shadow cast by a full meal will mask or overlap the diagnostic features of ulceration, besides rendering full control of the contents difficult In other words, the whitewashing process described will be almost impossible under this condition, and many small gastric ulcers are still being missed for the same reason As in gastric work, radiographs alone are of little diagnostic value, most jejunal ulcers being extremely difficult to record on a radiograph, even after they have been located on the screen

Under present conditions, radiologists should not give a diagnosis of an organic lesion of the intestinal tract unless it has been visualised on the screen—in other words, *direct* evidence must be forthcoming The value of the examination is in no way lessened because a distinction between, for example, a simple and malignant ulcer cannot always be discriminated The hand and eye *properly trained* are of greater diagnostic value than radiographs, and direct evidence of *gastric* lesions in nearly 100 per cent of cases is, I believe, possible in the near future if this fundamental fact is but thoroughly grasped and recognised

Clinical and Laboratory Notes.

ON THE USE OF WEDGES FOR ELEVATING THE LOIN IN GALL-STONE OPERATIONS

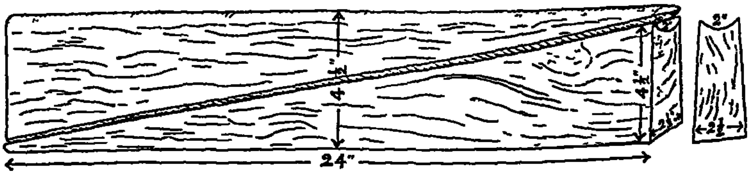
By G Grey Turner, M S Durh, F R C S Eng,

SURGEON, ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE

For nearly 20 years I have been in the habit of using wooden wedges for elevating the middle of the body in gall-stone operations to secure the Mayo-Robson position The wedges were originally devised for the elevation of the loin in operating on the kidney, hence the name "kidney wedges" by which they have come to be known in Newcastle I would not have thought of bringing this device before the notice of the profession had it not been that many friends, who also use the wedges, are enthusiastic about their utility

The wedges which I use are made of soft wood and are of the shape and dimensions indicated in Fig 1

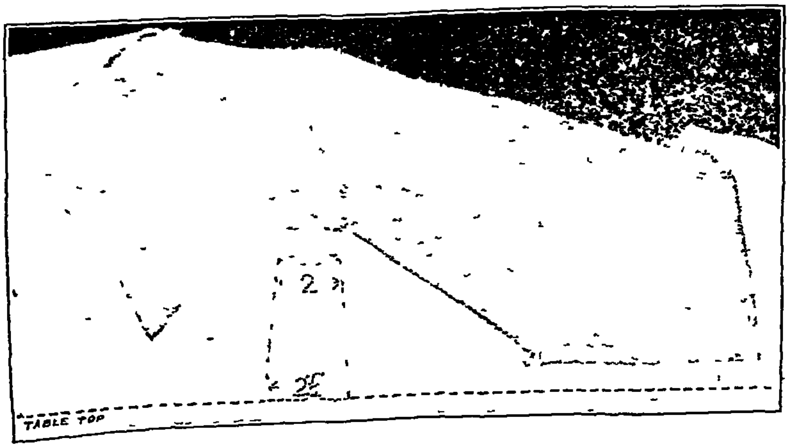
Fig 1



The principle involved is simple The wedges slide on each other, and are passed beneath the patient, one from either side of the operating table, so that when both are in position the patient is elevated by their conjoined height The groove in the top of the bottom wedge, and the under-surface of the upper wedge, ought to be very smooth, and it is a good plan to have this part of the wedges kept polished with some kind of furniture cream One of my difficulties has been to prevent this smooth surface being destroyed by the frequent washing or other cleansing to which theatre equipment is subjected on Sunday mornings!

The mode of application of the wedges is simple but important, for if they are not properly used, muddle ensues, and the wedges are apt to be discarded as clumsy and unsatisfactory As a matter of fact, when properly used, they are eminently satisfactory in every way When the stage of the operation arrives at which the surgeon wishes the loin to be elevated, the nurse takes the grooved wedge and passes it between the bottom sheet of canvas on which the

Fig 2



patient lies and the top of the table To do this properly the canvas is lifted up a little until the point of the wedge is introduced. The nurse now lays hold of the canvas with both hands and presses with her body against the base of the wedge, thus easily pushing the latter on until its point appears at the other side of the table The second wedge is then introduced in a similar way from the opposite side, its rounded surface being applied to the groove on the upper surface of the thin end of the wedge first introduced When it, in turn, is pushed home, the body of the patient is elevated by 4½ inches, which is the conjoined height of the wedges when assembled (Fig 2)

The process can be more easily carried out by two persons, one working from either side of the table When one person carries out both manœuvres, the surgeon must press against the wedge first introduced with his body, so as to prevent it getting displaced while the second one is being introduced from the other side The insertion of the wedges takes far less time to carry out than to describe If either is not properly introduced, or if one or other turns on its side, or is otherwise disarranged, then it, or both, should be withdrawn and reintroduced It is never necessary to lift the patient in order to put in the wedges, and in fact, the principle involved is grossly violated by any such attempt

With the wedges which I at present use I have never known any displacement occur after they have once been properly introduced, but I have known a narrower wedge fall on its side If that happens, it is very easy to withdraw both and to commence the process again The wedges have the advantage that they can be introduced at any part of any table at any stage of an operation, and can likewise be easily withdrawn when the incision is about to be sutured The rubber pads which have recently been introduced for placing on operating tables for the comfort of the patients have rather complicated matters; but we find that the wedges are as easily used as before if a strong canvas cover is placed between the table and the rubber pad The wedges are then introduced between the canvas cover and the top of the table as before These wedges are made and stocked by Messrs R McQueen and Son, Newcastle-upon-Tyne

VESICAL CALCULUS WITH NUCLEUS OF PARAFFIN WAX

BY ERNEST H SHAW, M R C P LOND,
DIRECTOR OF CLINICAL PATHOLOGY AND PATHOLOGIST, ROYAL NORTHERN HOSPITAL AND HONORARY PATHOLOGIST, HORNSEY COTTAGE HOSPITAL.

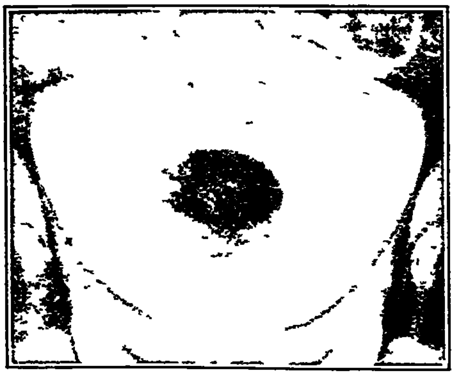
THE following case is reported on account of its rarity and general interest The specimen consists of a calculus, the centre of which is occupied by a mass of paraffin wax The stone was removed by operation from the urinary bladder by Mr Kenneth Walker, and the writer is greatly indebted to him for his permission to report the case

Clinical History —L. P aged 19 years (male), admitted to the Royal Northern Hospital on August 11th, 1925, under the care of Mr Kenneth Walker, complaining of burning sensation on micturition

Past History —October, 1924 patient first noticed burning sensation on micturition, and slight frequency and, a month later he observed a brownish colour of the urine He then consulted a doctor February 1925, pus and *B coli* were found in the urine, and vaccine treatment was undertaken No improvement occurred and about April the urine was examined for tubercle bacilli with negative result on two occasions Another specimen was examined by the same pathologist who used the Ellerman and Erlandsen method and tubercle bacilli were found He verified this on two subsequent occasions. The specimens of urine were collected with aseptic precautions but *not* through a catheter The patient subsequently underwent open air treatment for some months The youth stated that three years ago while boxing he was hit on the "kidney region," and afterwards passed blood

Present Condition —The burning sensation is still present, but much less than last year It is felt just above the pubes The stream stops suddenly occasionally Physical examination of chest and abdomen revealed nothing abnormal. X rays showed a large stone in the bladder Urine normal; no T B found, two specimens examined

FIG 1.



Calculus in the bladder

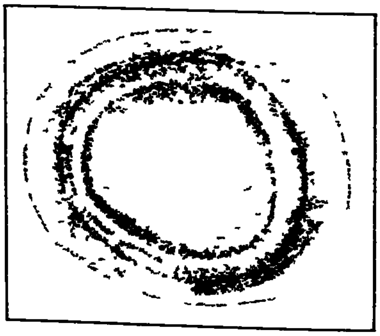
Operation (August 14th, 1925)—Suprapubic cystotomy. The stone was removed from the bladder, and no evidence of tuberculous disease was discovered After drainage with a rubber tube, the wound healed and the patient was discharged on Sept 9th.

Description of Stone

Flattened, ovoid in shape, measures 4 3 × 3 6 × 2 6 cm. Weight 32 g The surface is finely granular, whitish in colour with patches of light brown deposit On section the stone shows concentric layers of hard, somewhat brittle material, the centre being a solid mass of semi-translucent wax, roughly oval in outline, and measuring 1 9 × 1 2 cm From within outwards the layers of stone are a layer of white, soft, brittle material around the wax, and then several layers of hard light brown stone alternating with soft white rings. Surrounding these rings the outer part of the stone is white and hard for the most part, but soft crumbling patches are present in places

Chemical Composition —Mr H Skinner kindly examined the stone and made the following report —Stone: Composed almost entirely of phosphates The darker rings contain a little oxalate of lime in addition to phosphates Nucleus: Composed of pure paraffin wax with a melting point of between 53–54° C Burning gave the characteristic smell of paraffin wax In xylol the wax dissolved quickly and completely The wax was easily softened and moulded into any shape by the finger and thumb A suggestion that the nucleus might be adipocere was disproved by the above findings for this substance has a melting point between 61–67° C and is easily dissolved or emulsified by NaOH This chemical has no effect on the wax

FIG 2



The structure of the calculus after dividing it with saw

The identity of the substance forming the nucleus having been established it became necessary to explain its presence there The patient would not give any information on this point but there can be no doubt that it was passed along the urethra how long before the stone was removed it is impossible to tell Mr Walker states that wax has been found in the male bladder in other cases and patients have confessed to having collected candle 'drippings' moulded them into shape and pushed the material into and along the urethra Mr Skinner states that nearly all modern candles are made of the left hand is now to prevent, by gentle pressure, any of the meal passing further into the body of the stomach, for, if the pylorus is passed, shadows in the afferent limb of the jejunum will cause confusion. The business of the right hand is to dam up the emulsion in the first few inches of the efferent limb This manœuvre is not always easy to accomplish The opaque cream is now manipulated backwards and forwards through the stoma into the jejunum, and back again into the stomach This whitewashing process will cause the opaque substance to adhere to any ulcer crater present, showing itself as a black fleck or spot which remains isolated after the displacement of the contents by pressure This fleck, as in gastric ulcer, shows denser than the surrounding meal The penetrating type of ulcer is more usual and is easier to detect, as a nipple or bud-like projection on the jejunal wall This will also remain filled after displacement of the contents Pressure of the right hand is now released, allowing the contents to flow on into the remainder of the jejunum Six inches from the stoma may be considered the limit of jejunal ulceration The remainder of the meal is now swallowed and the rest of the stomach examined as a matter of routine

Ulcers may occur around the anastomosis or several inches from it in the efferent loop, usually just opposite the stoma itself. These may be multiple, and are seldom found on the afferent side. I have found that the majority of jejunal ulcers detected radiologically are in the angle formed by the greater curvature of the stomach and the efferent limb of the jejunum, (the gastro-jejunal angle, Fig 1, A) The closer the ulcer is to the anastomosis (gastro-jejunal ulcer), the deeper it will lie in this angle The true jejunal ulcer, usually of the penetrating type, is found as a rule projecting from the *inner* surface of the jejunum, well out of the gastro-jejunal angle Deep pressure in this angle will in many cases help to demonstrate an ulcer

Those unaccustomed to this examination will at first experience difficulty in detecting an ulcer among the numerous projections and isolated flecks that will be seen in the neighbourhood simulating ulcers, and the inexperienced are more apt to see ulcers that are not there than to miss the genuine lesion The shadow cast by a full meal will mask or overlap the diagnostic features of ulceration, besides rendering full control of the contents difficult. In other words, the whitewashing process described will be almost impossible under this condition, and many small gastric ulcers are still being missed for the same reason As in gastric work, radiographs alone are of little diagnostic value, most jejunal ulcers being extremely difficult to record on a radiograph, even after they have been located on the screen.

Under present conditions, radiologists should not give a diagnosis of an organic lesion of the intestinal tract unless it has been visualised on the screen—in other words *direct* evidence must be forthcoming The value of the examination is in no way lessened because a distinction between, for example, a simple and malignant ulcer cannot always be discriminated. The hand and eye properly trained are of greater diagnostic value than radiographs, and direct evidence of *gastric lesions* in nearly 100 per cent of cases is, I believe, possible in the near future if this fundamental fact is but thoroughly grasped and recognised

Clinical and Laboratory Notes.

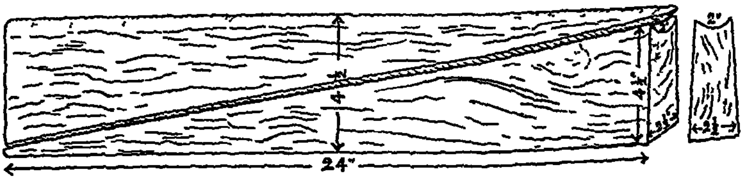
ON THE USE OF WEDGES FOR ELEVATING THE LOIN IN GALL-STONE OPERATIONS

BY G GREY TURNER, M S DURH, F R C S ENG,
SURGEON, ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

FOR nearly 20 years I have been in the habit of using wooden wedges for elevating the middle of the body in gall-stone operations to secure the Mayo-Robson position The wedges were originally devised for the elevation of the loin in operating on the kidney, hence the name "kidney wedges" by which they have come to be known in Newcastle I would not have thought of bringing this device before the notice of the profession had it not been that many friends, who also use the wedges, are enthusiastic about their utility

The wedges which I use are made of soft wood and are of the shape and dimensions indicated in Fig 1

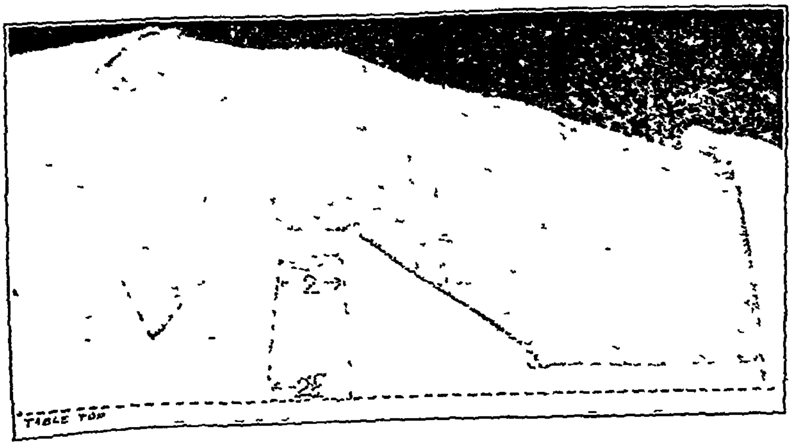
FIG 1



The principle involved is simple The wedges slide on each other, and are passed beneath the patient, one from either side of the operating table, so that when both are in position the patient is elevated by their conjoined height The groove in the top of the bottom wedge, and the under-surface of the upper wedge, ought to be very smooth, and it is a good plan to have this part of the wedges kept polished with some kind of furniture cream One of my difficulties has been to prevent this smooth surface being destroyed by the frequent washing or other cleansing to which theatre equipment is subjected on Sunday mornings!

The mode of application of the wedges is simple but important, for if they are not properly used, muddle ensues, and the wedges are apt to be discarded as clumsy and unsatisfactory As a matter of fact, when properly used, they are eminently satisfactory in every way When the stage of the operation arrives at which the surgeon wishes the loin to be elevated, the nurse takes the grooved wedge and passes it between the bottom sheet of canvas on which the

FIG 2



maternity hospitals on the same basis, and quoted a small local hospital where a consultant was retained at an annual fee of £21, in some years he had no work at all, in others he would have a few operations Dr Claxton proposed

> That a local authority may retain for a municipal maternity hospital the services of a consultant on a yearly salaried basis

Dr R C Buist (Dundee) said there were so many local difficulties that the question could not be settled for everyone, and proposed to refer the matter to Council

Dr Peter Macdonald (York), seconding this, quoted a case where the local authorities had appointed a consultant and had asked, and taken, the advice of the local division of the B M A on the form and remuneration of the appointment That sort of local option was very desirable

The meeting agreed to refer the question to Council

Dr Bone proposed on behalf of the Medico-Political Committee

> That the Representative Body strongly objects to the practice adopted by some public bodies of asking medical practitioners to tender for appointments, and that advertisements of such appointments be not published in the *British Medical Journal*

In answer to questions he explained that by "tendering" he meant advertisements in which the applicants were asked to state what salary they would accept The motion was carried, as was the further recommendation of Council

> That, having reviewed the whole situation as regards complaints and charges in courts against medical practitioners, the Representative Body does not consider that it is necessary for the Association to take any action in the matter of such complaints and charges

Factory Medical Service

Dr Bone moved on behalf of Council

> That a medical service of occupational hygiene should form no exception to the Association's policy that the administration of all health services should be unified first centrally and then locally

He said that the matter had been very fully discussed by a joint committee and there had been no dissentient voice raised against this proposition

Dr F W Dearden (Manchester) asked what would be the attitude of the Association to a Factory Bill, among the provisions of which was a proposal to hand over any part of the certifying factory surgeon's duties to the local authority as at present constituted? Dr Bone replied that the Association would not agree to such provisions, and the motion under discussion covered that eventuality It was carried

Officers at Orthopædic Clinics

The Council recommended

> That for part-time work at ordinary orthopædic clinics the remuneration of the medical practitioner should be £2 12*s* 6*d* per session of not more than two hours, provided there is a limitation to be agreed locally, of the average number of new cases to be seen in each session

It was proposed by the Chairman, in the absence of Dr E Solly (Harrogate), and seconded by Dr D Roxburgh (London)

> That the words "not less than" be inserted before "£2 12*s* 6*d*"

Dr H B Brackenbury pointed out that these words did not occur in any other corresponding clause in the scheme Dr Bone said that if the whole schedule was to be altered it should be done deliberately and not as a side issue The amendment was lost

In reply to a question as to why the fee should be greater than that given to pensions doctors and other medical officers of clinics, Dr Bone pointed out that it was a specialist service and the fee corresponded with that for two other specialist clinic services—viz, ophthalmic and anæsthetic work The motion was carried

Royal Commission on Local Government

The Deputy Chairman, Dr C O Hawthorne, took the chair, while Dr Brackenbury spoke to the motion proposed by the Chairman of the Medico-Political Committee

> That the following recommendation of Council be adopted. That the Memorandum of Evidence submitted to the Royal Commission on Local Government on behalf of the Association be approved

Dr Brackenbury said that there were certain fundamental principles laid down by the Association which lay at the basis of the memorandum The first was that health services should be separated as completely as possible from other administrative services which were not of a health character—*for instance*, that the health functions of Poor-law guardians should not be complicated by relief work The second was that when these health services had been separated they should be combined as far as possible with all other health services, so that all the health services of the country, centrally and locally, should be under one form of administration and under one local authority. The question arose as to what body and area was most suitable for this authority The ideal was that all present divisions should be swept away and the country parcelled out afresh into areas, each with a large town as centre This was unattainable, so the suggestion made was that all health authorities should be compelled so far to work together as to approach as nearly as possible the ideal of unification The machinery by which this should be done was a fundamental point Those who had drawn up the memorandum believed that, as had been done under the Education Act, the best way would be to have a statutory health committee of a composite character, elected by local doctors, to advise and report, without touching finance This committee would have on it representatives of the medical practitioners and such other bodies as were experienced and interested in the health services of the local area Unification of health administration could not be obtained if there were in any part of the country a superior and a minor health authority, the memorandum therefore looked with disfavour on the proposal of the Ministry of Health to give to county councils supervision and, largely, control of all health matters in the hands of urban or rural districts or in county boroughs within their area He instanced a borough like Willesden, of some 200 000 inhabitants, which had been the successful sanitary authority for many years The county council would have had no experience whatever of sanitation, and the transference to it of supervisory authority must lead to friction, overlapping, disturbance, and inefficiency Rural areas with scattered and sparse population and few funds were more difficult, a satisfactory service might be attained either by giving the county council a supervising and controlling position or by making the small rural area give up its authority to the county council which would thus become *the* health authority for the rural area. The memorandum preferred the latter

Dr J Middleton Martin (Gloucestershire) proposed an amendment

> That the following words be added, "but that further consideration of the matter by the Council be given, if possible, before any Parliamentary or political action be taken"

He said that in Gloucestershire the health services had been successfully put in the hands of local practitioners and he was in favour of this, but took exception to any extension of their representation on the new health authority It had been found that the opinion of a medical advisory committee, presented as a considered report, had much more weight than the individual voices of members of the executive body People were too inclined to think in terms of London, which required exceptional treatment, he suggested making the county council the responsible authority, with exceptions where desirable

Dr R A. Lyster (Hampshire) seconded the amendment, and said that it was outrageous for the meeting to endorse a complicated memorandum which would commit the Association to a conflict with the Ministry of Health on a subject only remotely connected with medical affairs The great urban paraffin wax Tallow candles are not used so much as formerly

Commentary

On reviewing the clinical history, it will be noted that the pathological findings in the urine reveal apparently three phases (1) pyuria with infection by *B coli*, (2) the same and tubercle bacilli; (3) normal urine with stone in the bladder

As the urine was free from pus and organisms at the time when the stone was removed, and the bladder wall was found to be normal, an interesting field for speculation is opened up in regard to the presence of tubercle bacilli found in the urine during the second phase Four possibilities present themselves (1) a tuberculous lesion of the bladder wall had healed without visible scarring, (2) one or both kidneys are tuberculous, (3) contamination, (4) mistaken identity

(1) Must remain just a possibility (2) no evidence to prove this during the patient's stay in hospital, (3) contamination of the urine by tubercle bacilli during its collection need only be mentioned to be dismissed; (4) the question of mistaken identity is, however, one which has to be considered, as all workers in clinical pathology are aware of The smegma bacillus at once occurs to one's mind, and it seems possible, if not probable, that this was the organism found in the urine in what has been labelled the second phase of the case As the urine was not collected through a catheter, the possibility of smegma bacilli being included in the urine passed through the meatus must be taken into consideration

Incidentally, the writer wishes to observe that the idea that smegma bacilli lose the red colour deposited by carbol fuchsin on well washing the films with methylated spirit is not always reliable He has repeatedly experimented with films of the smegma bacillus—treated them with acid followed by spirit and found the bacilli stained a bright red Another point which is of importance to the laboratory worker is the curious fact that *B coli*, when lying on loose epithelial (squamous) cells in the urine, seem to have an affinity for carbol fuchsin It is not very uncommon to see red bacilli on a squamous cell with large numbers of others stained blue (with Löffler's stain) in the other part of a field This apparent acid-fast property of *B coli* is no doubt due to incomplete washing in acid and methylated spirit, but it arouses one's curiosity and causes speculation as to whether these bacilli have absorbed a certain amount of fatty material from dead and degenerated epithelial cells on which they lie

It will be remembered that tubercle bacilli are said to possess a certain amount of fatty substance in their covering or body, and this is given as an explanation for their acid-fast property

To continue with one's speculation over this curious and interesting case, might the *B coli* remaining in the bladder for some time have absorbed some of the paraffin wax, and in this manner been able to retain the carbol fuchsin stain like the tubercle bacillus?

The accompanying X ray photographs show the position and structure of the calculus

THE PRINCE OF WALES'S INTEREST IN HOSPITALS During the past fortnight the Prince of Wales has been showing active interest in hospitals and their work He attended the centenary celebrations at the West Herts Hospital at Hemel Hempstead, and laid there the foundation stone of a new maternity ward Later on he visited the Isle of Wight County Hospital at Ryde, where he presented Mr B O Cochrane with a silver model of a galleon on behalf of the staff of the hospital, of which he has been treasurer and chairman At Ventnor he opened the nurses' home at the Royal National Hospital for Consumption and Diseases of the Chest, of which His Royal Highness is patron On his return to Portsmouth, to be formally admitted to the freedom of the city he visited the Royal Portsmouth Hospital, to which he presented the masses of roses with which he had been pelted during his progress through the streets

BRITISH MEDICAL ASSOCIATION

ANNUAL MEETING AT NOTTINGHAM

(Continued from p 198)

REPRESENTATIVE MEETING

MONDAY, JULY 19TH

Practitioners' Fees in Municipal Maternity Hospitals

THE Chairman of the Medico-Political Committee, Dr J W BONE, moved on behalf of the Council

That where the local authority makes provision for the institutional treatment of maternity cases, this should be mainly or primarily for serious cases of antenatal complications, for cases requiring major obstetric operations, for cases where isolation and treatment of septic infection is specially indicated and other cases where the home conditions are unsuitable or dangerous for confinements

This merely made what had already been resolved at Bath the policy of the Association Dr BONE also proposed

That where a general practitioner is called upon to render assistance at a confinement in a municipal maternity hospital, the fees payable to such practitioner should be in accordance with the scale of fees approved by the Ministry of Health for the payment by local supervising authorities to medical practitioners called in on the advice of midwives under Section 14 of the Midwives Act, 1918

To this Dr R FORBES proposed an amendment on behalf of Gateshead

That the whole of the last clause be deleted and the following substituted therefor The local authority shall be responsible to such practitioner for his fees until such time as the patient is removed from the hospital

He pointed out that under Section 14 of the Midwives Act, 1918, a medical practitioner could obtain payment when called in by a midwife only up to the twenty-eighth day It was quite conceivable that complications might arise so that attendance was necessary for a much longer period

Dr BONE said that the point was a good one, and he was in full sympathy with it, but it was necessary to bargain and to deal with other people Already a good scheme and good remuneration had been secured, and it was not easy to remove such a limit at a time when economy was the idol of Government departments He suggested that the matter be referred to Council Dr Forbes accepted this

Dr C F T SCOTT (Willesden) proposed a verbal emendation

That the words "not be less than" be substituted for the words "be in accordance with,"

which was carried

Dr BONE proposed and carried the recommendation of Council

That where a consultant is called in by the practitioner in charge of the case the fee should be for the consultation not less than 3 guineas and for a major operation not less than 10 guineas

Dr FORBES said that Gateshead felt that a consultant spent less time and had less trouble in a municipal hospital, where everything was prepared for him, than in a private house, and they wished to make the fee £2 2*s* It was a very important point, and in some areas this might be too little, there must be a revision on a territorial basis

Dr E W MASTERMAN (London) said that it would be very undesirable to have a different arrangement in municipal maternity hospitals and Poor-law hospitals, as in many places the former were being started in connexion with the latter He suggested referring the matter to Council and inserting the words "and mileage as required" but Dr BONE said he refused to listen for a moment to any alteration, the scheme had been carefully considered and the fee was reasonable The "territorial" argument was a fallacious one, and would be fatal to central work

Dr E I CLAXTON (Liverpool) remarked that the meeting had already agreed that the Council should consider a scheme for yearly agreements for consultants in Poor-law hospitals He wished to put the municipal

SIR RICHARD LUCE said that it would be bad policy to expect that medical men should be treated on different terms from other owners of nursing homes Evidence before the Committee had proved that there was grave reason for investigation and registration, and the fact that members of the medical profession were under the control of the General Medical Council was not much help as it was most unlikely that patients would ever charge a medical man before that body

Drug Addiction

In proposing the adoption of the remainder of the supplementary annual report under "Medico-Political," Dr BONE drew attention to the report of the Departmental Committee on Morphine and Heroin Addiction the recommendations of which corresponded very closely with the desires of the Representative Body as expressed at Bath

Dr C O HAWTHORNE said that it was a very serious thing that it had now become law, partly on the representation of the Representative Body, that a practitioner who was believed to have offended against the Dangerous Drugs Act could be haled before a special tribunal of three doctors with a legal assessor and not before the ordinary courts of the land This tribunal could recommend the Home Secretary to remove his name from the list of those permitted to prescribe these drugs There was no guarantee that the evidence could be challenged by a legal representative of the accused This arrangement, on the one hand, offered the doctor benefits which it did not confer on other citizens, such as pharmacists, who were even more intimately concerned with the Act, and, on the other hand, removed him from the solid protection of the English law

Dr E K LE FLEMING (Wimborne), speaking as one who had given evidence before the Committee, pointed out that it had been presided over by Sir Humphry Rolleston, who was not likely to neglect the best interests of the profession This clause of the recommendations was dealing with a particular case, the doctor who had become a drug addict, and hitherto such a man could only be allowed to go on until he came before the courts The Committee thought that if it were possible to interpose a tribunal with a strong medical element which would protect him from himself and protect his patients by preventing him from prescribing dangerous drugs in excess, it would be acting in the best interest of both

Dr E R FOTHERGILL (Brighton) drew attention to what he called a most objectionable position In a recent case Sir Travers Humphreys had defined justifiable use of dangerous drugs as a prescription given by a duly qualified medical practitioner when required for medical treatment This meant that the onus of proof that the drug was given in the course of medical treatment lay on the prescriber, and the whole question of the freedom of the profession to treat patients could come under the jurisdiction of the Home Office

Dr BONE replied that Dr Fothergill's anxiety was due to incomplete information It was clearly specified that there were certain circumstances in which it was perfectly legitimate to use these drugs where their withdrawal would lead to serious symptoms such as could not be treated under the conditions of private practice, and for those people who could live comparatively normal and useful lives so long as they took a certain quantity of their drug of addiction There was ample evidence that certain doctors were practically selling these drugs to addicts without attempt to cure, and the legislation was designed to stop that sort of thing The Committee had been advised by the great legal experts of the Government and believed that the clause effected this end

Certification under the Workmen's Compensation Act

Dr G F SHEPHERD proposed on behalf of South Shields and Tyneside

> That the Representative Body is of opinion that, while the obligation of certification of injury under the Workmen's Compensation Act is in the first instance placed upon the employer and there is no obligation whatever under the National Health Insurance Acts to provide compensation certification, nevertheless it is often found that the employer, or his agents, or his covering company, requires initial certification either at no expense or wrongfully at the expense of the injured person, and that it is therefore advisable that a uniform and universally used form of certification be employed in all cases in order to conform to the law ; and that the Council be instructed to take such steps as may be necessary to bring a uniform certificate and system into being at the earliest possible moment

He said that the system of giving certificates for nothing was thoroughly bad The whole question of certification remained as it was in 1913 and should be gone into at the same time

Dr BONE replied that a solution of this problem had been sought for a long time The bodies concerned were chiefly large insurance companies, and it had been found that there was an Accident Offices Association which represented them all The Council was in communication with this organisation about this matter There were difficulties, as in some districts the doctors had acquired the habit of issuing sixpenny certificates and did not wish to be deprived of this arrangement He suggested referring the matter to Council, which was agreed

Antenatal Work and the Midwives Act

It was proposed by Dr T R DAVIES, on behalf of South-West Wales

> That the Council be instructed to consider the advisability of pressing for the amendment of the Midwives Act, 1918, in order to secure that local authorities be made responsible for payment for antenatal work

It was decided to refer the matter to Council for consideration

Medical Defence

Two motions, urging that the time had come for defence societies to issue policies covering a principal for the acts of his assistant or locum tenens, were withdrawn, on the announcement by Dr A LYNDON (Hindhead) that the two great medical defence societies were very conscious of the growing and legitimate demand made by their members for such protection, and the following decisions had recently been arrived at by the Medical Defence Union —

(*a*) That the Medical Defence Union will defend the principal, if he is a member of the Union, should action be taken against him arising out of the acts or omissions of a locum tenent, even if the locum tenent is not himself a member of any defence society ,

(*b*) That a reciprocal arrangement had recently been entered into between the Medical Defence Union and the London and Counties Medical Protection Society, whereby each society will defend its own member in an action arising out of the acts or omissions of an assistant or locum tenent, who is a member of the other society, as if the assistant were a member of the same society as the principal ,

(*c*) That as regards a subordinate medical officer of a hospital, the same procedure will apply in the case of members on the staffs of hospitals against whom actions are brought arising out of the acts or omissions of duly appointed subordinate medical officers , and

(*d*) That if the principal, being a member of one society, is sued jointly with the assistant or locum tenent or subordinate medical officer, who is a member of the other society, each society will defend its own member and the two will collaborate in the conduct of the case

It was proposed by Dr J STEVENS, on behalf of Edinburgh

> That the Council be requested to take all necessary steps as soon as possible to deal with the situation that has arisen as a result of the findings of the jury in the Harnett *v* Fisher case, with the view of protecting the interests of the medical profession

Dr ROXBURGH, supporting the motion, said that it was scandalous that the profession should be subjected to legal proceedings for issuing bona-fide certificates

The motion was referred to Council

Motor Licences

Dr S. MORTON MACKENZIE proposed on behalf of Reigate

> That the Council be instructed to use all possible pressure to obtain such amendments to the Motor Licence Regulations

boroughs could safely be left to look after themselves While the memorandum was very good in some places, it betrayed an amazing and ludicrous lack of knowledge in some of its points

Dr **BRACKENBURY** replied that Dr Buchan had described the memorandum as the best and clearest and most satisfactory statement on the subject he had ever read or hoped to read He challenged Dr Lyster to mention any statement that revealed lack of knowledge The memorandum expressly recognised London as exceptional The term " county council " must not be reserved for rural councils

Dr E **WILLIAMS** (Cardiff) said that there were enormous variations in rural England , some services were essentially large group services, while others were essentially local The impetus to Poor-law reform was not any desire for unification of medical services, but was financial

Dr R P **GARROW**, medical officer of health for the non-county borough of Chesterfield, pointed out that large urban district councils were not confined to London He asked the meeting to accept the memorandum in its entirety, the most essential point being that the county council should not have supervision over those large urban districts or boroughs

Dr A T **JONES** (Glamorgan) said that Dr Williams might represent Cardiff, but not the large industrial districts of Wales, and he considered it would be quite impossible for the Glamorganshire County Council to administer these things in its county.

Dr H G **DAIN** (Birmingham) supported the amendment, saying that before the memorandum received the whole-hearted support of the profession the general practitioner would want to see more clearly what his position was going to be under the reconstituted authority The suggestion now was that the local authority's health department, which had grown up for a very definite purpose, should absorb a large amount of the clinical side of medicine with which it had hitherto had little to do Where would the insurance practitioner stand when employed for at least one-third of his practice by the local health authority ? Many general practitioners would object to being employed by the medical officer of health or the present health committee with its traditions and officers , this might well cause a revolution

Dr J. **ROBINSON** (Manchester) remarked that all the biggest urban district councils were outside London , he feared that overlapping of the duties of the medical officer of health under the local authority and the county medical officer would lead to friction and financial loss , there should be complete unification.

Dr. **EUSTACE HILL** said he wished to plead strongly for a reconsideration of the memorandum ; he was convinced that the Association was on the wrong lines He welcomed any scheme to improve the present administration, which was rotten , the proposals of the Ministry of Health allowed the county council to delegate anything they liked, which would cover such cases as Willesden They could divide the county into areas, appoint additional medical officers of health, and transfer to them the duties at present done centrally, such as tuberculosis and venereal disease work He considered that the memorandum had been drawn up by someone who was not thoroughly conversant with the conditions

The amendment was carried

Dr **BRACKENBURY**, speaking to the substantive motion as amended, said that Dr. Eustace Hill was wrong in saying that county councils could delegate their powers The confusion arose because in the Minister's proposals county councils were given supervision over all matters of health within their areas, but the only powers they could delegate were those transferred to them from the Poor-law guardians , they could not delegate their supervisory powers He had been asked the relationship of this memorandum to a State medical service It was evident that local authorities must in future take a greater interest in health administration and clinical questions, must employ local private practitioners in all the auxiliary services and clinics *as far as possible*, and not work them through whole-time medical officers In this way the proposed rearrangements would act as a strong bulwark against any State medical service

The motion was carried, and Dr Brackenbury resumed the chair

The B M A and Parliament

Dr **BONE**, in proposing the adoption of the remainder of the annual report under " Medico-Political," said that there was some difficulty in getting the views of the Association expressed in Parliament There would be no success until the fund for supporting the B M A 's own representatives was continued

Sir **RICHARD LUCE**, speaking as a member of the Committee of Medical Members of Parliament explained that that Committee practically never took any coordinated action, as it contained representatives of all parties, who could rarely be unanimous There were three Bills at present on the table of the House of Commons The first, referred from the House of Lords, dealt with the reform of the Coroners' Law, and already contained many recommendations in accordance with the policy of the Association The Government had conceded the payment of resident medical officers for post-mortem examinations, and that coroners should be either doctors or lawyers. The profession still wanted improvement in the rates of pay for evidence in the coroner's court, and an amendment was to be brought forward on the lines desired by the Association, except that a combined fee of 4 guineas (instead of 4½ guineas) was to be recommended for the post-mortem examination and relative evidence There was sure to be great opposition. The coroner could already order and pay for an autopsy without calling the doctor in evidence, and it was now suggested that he should be entitled to ask for a report and, if this was wholly satisfactory, dispense with an inquest For such a report a fee of half a guinea was suggested The second Bill was Colonel Fremantle's on the registration of births and deaths As this was a private member's Bill it could not carry any financial consideration For this reason it was not possible to push the B M A policy of a *compulsory visit to the deceased before* granting a certificate The Bill had gone a long way, but was opposed by a section who wanted to compel the doctor to make the visit without fee The notifications would be by post and private There was also a proposed regulation as to the time a body might be left unburied

It was proposed by Dr P **HAMILL**, on behalf of the City Division, and carried

> That the Representative Body is of opinion that all medical officers—honorary or otherwise—of hospitals or rate aided institutions be entitled to receive fees on the same scale as other practitioners for post-mortem examinations and attendance as medical witnesses at inquests

Dr. **BONE** remarked that this was already the policy of the Association

Dr **ROXBURGH** asked whether the death certificate proposed was to be private and privileged If not the Registrar-General would not get accurate information, and it was most important that he should

Dr **BONE** replied that a private certificate had been part of the policy of the Association for years, but would involve considerable expense, and it was essential for the passing of the Bill that it should not cost money The present certificate represented an attempt to get at no cost a semi-confidential registration of the actual cause of death It was not open to the relatives, but placed in a sealed envelope for the Registrar. The only difficulty would arise if an insurance company required to know the cause of death and obtained permission to get a copy of the certificate The Association had neither pressed nor opposed it

Registration of Nursing Homes

Dr. **BONE** proposed that the Memorandum of Evidence submitted on behalf of the Association to the Select Committee on the Registration of Nursing Homes be approved

The early treatment of otitis media had recently become relatively hopeful, and it was most important that advice should be obtained as soon as there were signs of ear trouble

Dr **PETER MACDONALD** (York) said that the value of the motion depended on the extent to which it would help to create a public opinion Parents and school-teachers, especially house-masters needed education as to the importance and urgency of "running ears" He was not, however, certain that Marylebone's method was the best and suggested referring the matter to Council

Dr **DAIN** said he was in full sympathy with the necessity for an educational campaign, but thought that what had been said had done all that could be done No approved society would be in a position to consider any additional benefits for five years

It was agreed to pass to the next business

Dr **DAIN** then proposed

That the Representative Body regards as serious the situation which arises in consequence of the negative replies of the Ministry of Health in connexion with the methods and machinery for dealing with complaints against insurance practitioners, and pledges itself to support proposals (*a*) to secure equal justice for practitioners as for insured persons and approved societies, (*b*) improved methods for dealing with complaints of minor importance, and (*c*) resistance to any claims of the Ministry of Health or of insurance committees to judge as to the propriety of the treatment adopted by a practitioner in attending his patient or the relative degree of care and skill shown by a practitioner in such attendance as compared with that of other registered medical practitioners

He said that the motion arose from the strong feeling of the Insurance Acts Committee that the present arrangements were unsatisfactory and needed considerable modification It was impossible for anyone to decide on read evidence alone that a doctor had not done all that he should have done and still more to impose a penalty The Ministry had been pressed most strongly either not to deal with such cases or else, if they did to allow the doctor an appeal On account of a lack of sympathetic assurance from the Ministry he asked the Representative Body to carry the motion in support of their colleagues engaged on National Health Insurance work

Dr C H **HALL** (West Hertfordshire) seconded the motion and read a letter from a K C who had resigned his position as vice-chairman of the local medical service subcommittee because of his indignation at the attitude of the Ministry, which he described as "contrary to the ideas of justice in which I have been trained" The letter went on to describe the case in question, which was that of a busy doctor who dictated his prescriptions over the telephone to his qualified dispenser, who signed them On being brought before the committee the doctor admitted that he had overlooked the regulations and undertook that it should not occur again and expressed his regret. There was no evidence that anyone had been injured by his practice in any way The committee unanimously agreed that a caution would meet the case The Ministry officials interviewed the doctor and then met a deputation from the local committee They stated that the doctor had broken his contract and must be fined for the breach whether there had been damage or not, they even intimated that there ought to be a scale of deductions for different breaches of the terms of service It was contrary to all legal training and teaching that persons who had not been present at the hearing should decide that a penalty should be inflicted when those who were present had found otherwise The writer of the letter concluded that so long as this system prevailed he felt he would be out of place in assisting in its administration

Mr E B **TURNER** proposed to strengthen the resolution by inserting the words "to organise a most strenuous" before the word "resistance," and this was carried He said it was a tremendous slight on the profession as a whole and absolutely preposterous for any insurance committee as at present constituted to say whether a doctor's treatment was right or wrong

The amended motion was carried unanimously.

State Medical Service

It was proposed by Dr **MUIR SMITH**, on behalf of Eastbourne

That the Representative Body is of opinion that no scheme of a State national medical service can be acceptable to the profession which fails, in principle, to recognise (1) the equitable claim of the practitioners undertaking to a similar measure of that protection which the law affords to unindentured contracts for service, and (2) the entitlement of the practitioner to the right of appeal to a court of civil jurisdiction on questions of administrative procedure

Dr **DAIN** said that the evils feared by Eastbourne were entirely imaginary, and the motion was rejected

In the course of the afternoon it was announced that the following eight members of Council had been elected Drs J W Bone, H G Dain, Mr W McAdam Eccles Drs E R Fothergill R Langdon-Down Sir Richard Luce, and Drs J A Macdonald and G W Miller

TUESDAY, JULY 20TH

Public Health Appointments

The Chairman of the Public Health Committee proposed on behalf of Council

That the Representative Body is of opinion that it is inadvisable and improper that whole-time medical officers engaged in public health work should be required, without suitable extra remuneration to undertake medico-legal or other duties not directly concerned with their duties as officials of local health authorities

and also

That with regard to salaries (under the scale of Minimum Commencing Salaries for Whole-time Public Health Appointments) for non-resident public health appointments, subsistence allowances be regarded in the same manner as travelling expenses—i e, as being included in the reasonable expenses properly incurred in the course of the duties of the appointment—which cannot be regarded as being part of the salary

Both these motions were carried

Dr E **SOLLY** proposed on behalf of Harrogate

That the remuneration of the medical superintendent (including the responsible medical officer) of a Poor-law hospital should be based not on the number of assistants which the board of guardians provides to help him in his work, but on the number of beds in the hospital and on the nature and extent of his responsibilities

The motion was supported by Dr **D'EWART** and Dr **MASTERMAN**, and was carried

In proposing the adoption of the annual report under "Public Health and Poor Law," the Chairman of the Committee pointed out that the Association had obtained the scale salary in 138 out of 173 public health appointments considered during the year

Public Education in Health

It was moved by Brighton (Dr E R **FOTHERGILL**):

That the Council be instructed to consider and report on how branches and divisions of the Association, as voluntary bodies, could make their contribution towards public education in health as advocated by Sir George Newman in his memorandum (issued in January, 1926) addressed to the Minister of Health.

Dr Fothergill said that the work of the Association in breaking down individualism and exclusiveness and safeguarding the proper interests and the honour and rights of the profession had won for it the respect and confidence of governments and the people they governed This achievement opened the door towards its second ideal—viz, preventive medicine. Much had been done centrally, and it was now important to see if more could not be done locally

The motion was passed

Advertisements Requiring Membership of a Medical Organisation

Dr **LANGDON-DOWN** moved

That it be an instruction to the Council to refuse advertisements of appointments which make it a condition either that the applicant must already be, or if successful in obtaining the appointment must become, a member of a professional organisation, society, or union, other than a society for individual medical defence

He said that these advertisements admitted the interference of lay bodies on a matter of purely private and individual concern connected only remotely with as will allow medical practitioners to transfer temporarily their licence to a second car if the first be out of use

He said that doctors were worse off than ordinary car users who could often postpone their journey if the car was out of order Hiring was uneconomical and most doctors had to keep two cars, with a second licence at an increased rate, although the two cars were never both in use Motor insurance companies met the doctor's difficulty by insuring the second car at a reduced cost and rapidly transferring the first insurance to the second car without any expense when the first was laid up

Mr E B **Turner** said that the policy of the Association was to get back the petrol tax From what the Chancellor of the Exchequer had said recently it appeared that this might soon be obtained, in which case the injustice would cease to exist Practitioners could do far more by attacking their respective M P 's on the subject than the Central Council could do

Dr L G **Glover** (Hampstead) remarked that it did not seem well known that it was possible to take out a quarterly licence for the second car, and if at the end of the quarter the car had never been used the licence was renewed free of charge

Dr **Bone** said that the substitution of the petrol tax for the car tax was the Association's policy, and it would be best to keep to that Nor did he care to go as a mendicant to the Government asking for special concessions which would be thrown in the profession's teeth when they went at some other time to ask for their rights Other professions required the use of a second car and all should be treated alike

The motion was rejected

Medical Insurance

It was proposed by Hastings

That the Council be instructed to consider the advisability of instituting a scheme of insurance for members of the B M A on similar lines to that afforded to members of the British Dental Association by the Dentists Provident Society.

Dr C L **Morgan** outlined the scheme in force under the Dentists' Provident Society.

Dr **Bone** said he did not think there was any demand for such provision as there were already many excellent schemes provided for medical men

Mr **Bishop Harman** pointed out that in 20 years less than 800 dentists had joined their Association, and its reserve fund was only £2000, and that the professional risk of dentists was the smallest of any group of workers, while that of doctors was one of the greatest General insurance companies could meet it by diluting doctors with other professions He did not think any scheme of insurance would be practicable

The motion was rejected

Use of Pituitrin by Midwives

Dr J **Hudson** proposed for the North of England branch

That midwives should not be allowed to use pituitrin under any circumstances,

saying that it was a potent drug which should not be in the hands of women with six months' training

Dr **Lyster** said he wished the Representative Body would persist in sending up such recommendations to the Midwives Board as in time they would produce their effect The attitude of the Board was that the midwife was taught and accustomed to use certain drugs in her training, and therefore she should be able to use them in her practice She had to enter them in her register, so that the extent to which she used them could be ascertained This would be satisfactory if there were any organised and systematic inspection of midwives, but, in fact, it was most imperfect and perfunctory, and afforded little or no protection to the public.

Dr **Bone** said that Dr Hudson was preaching to the converted The Council had taken vigorous action The Minister of Health had expressed the opinion that pituitrin should only be used by a midwife under the direction of a doctor, but the Midwives Board took up the attitude that it did not interfere with its midwives beyond demanding a record of drugs used The only way to produce an effect was to get information as to how extensively pituitrin was employed and find some case or cases where danger or damage had resulted from its use ; pious resolutions were useless

Dr P **Hamill** moved an amendment

That the words " pituitary preparations " be substituted for the word " pituitrin "

He pointed out that pituitrin was a registered trade name, and if the motion were passed in the proposed form there would be nothing to prevent the use of infundin or any other form of pituitary extract This amendment was carried The same speaker suggested that it was undesirable that there should be any suggestion that the profession put anything in the way of the use of substances that might save life, and in remote districts it might take a long time to get a doctor His division therefore proposed -

That the words " except in case of grave emergency and after medical assistance has been summoned " be substituted for the words " under any circumstances "

This amendment was lost, Dr **Bone** saying that he thought this qualification would be impracticable.

The motion was carried

Treatment of Rheumatic Children

Dr E A **Starling** proposed, and Dr E R **Fothergill** seconded

That this meeting requests the Council generally to consider and report upon the present position and probable future development of organised schemes for " the treatment of physically crippled children " (infancy up to 16 years of age), and of " children suffering from actual or potential rheumatism and/or heart disease," and in particular to consider the following suggested governing principles (*a*) the selection of patients should be mainly through the various branches of the public health service, (*b*) the clinical treatment should, wherever possible, be by means of private practitioners and voluntary hospitals

Dr Starling said that many schemes had been put forward and discussed Many branches of clinical work had been handed over to whole-time public health officers, and it was most important that their number should not be added to The treatment of rheumatic children was very important, and it would be wise for the Association to consider the matter and formulate their attitude

Dr **Roxburgh** said that if any part of clinical work and experience were taken away from the general practitioner a contribution was made to his inefficiency

National Health Insurance

Dr H G **Dain** proposed the adoption of the annual report under " National Health Insurance " He said that the Royal Commission had reported and the Government had produced a Bill that made medical benefit a first charge on the funds The Committee had been very concerned by the tremendous increase in work that was called for from the National Health Insurance doctor, and it would not be long before the money would be insufficient to pay for the services asked It was not likely that the other recommendations would be actively considered this year, and the Committee did not think it wise to raise any question of fees under present circumstances

It was proposed by Marylebone Division (Dr W. **Griffith**) ·

That on account of the widespread disabilities caused by diseases of the nose, throat, and ear, the Council be instructed to point out to the approved societies the importance of adding the payment of the whole or part of the costs of oto-rhinological and laryngological treatment as an additional benefit

He said that his division was anxious that the position of the insured patient should not be worse in any way than that of the private patient and that additional benefits should be available at the first possible moment

Dr **Christine Murrell** (Kensington) supported the motion, saying that the eye made a greater sentimental appeal to the public than the ear, and it was the duty of the profession to point out that disabilities of hearing were as great or greater than those of sight in medicine Sir Berkeley Moynihan who eloquently proposed "The City of Nottingham," enumerated some of the medical names for which the nation owed Nottingham a debt of gratitude, and rejoiced in the municipal devotion to art The passion for beauty, he said had always afforded a refuge from professional lassitude, and those who were developing the local University were raising up memorials to themselves in the grateful hearts of the people Alderman Foulds responded for the city, describing himself frankly as one who had never been a friend of doctors Dr Brackenbury, as Chairman of the Representative Body, proposed "Our Guests" describing himself as "proud of our associates as well as of our Association" Response was made by Mr L E Barnett, F R C S President-elect of the Australasian Congress 1927, and by His Honour Judge R W Turner Sir Humphry Rolleston proposed the President in well-turned phrases, lauding the sportsman's training for the great game of life, and in reply Mr Hogarth thanked all who had grudged neither time nor trouble to make the meeting a success, mentioning especially the name of the honorary local general secretary, Mr. A. M Webber

Excursions and Social Amenities

The Representative Body were entertained for the night of Saturday, July 17th by the Corporation of Buxton Over 300 guests took dinner in the Palace Hotel under the presidency of the Mayor of Buxton Alderman T H Cooper, who proposed the health of the Association and urged the importance and usefulness of British spas The Deputy-Mayor, Dr C W. Buckley, replying to the toast of "The Corporation," proposed by Mr Hogarth, spoke of the great amount of damage done by rheumatism and the necessity for further investigation On Sunday the party were conducted over the spa and then conveyed in motor chars-a-banc over the Cat and Fiddle pass and via Chatsworth Park and Haddon Hall to Rowsley, where they rejoined the special train for Nottingham In addition to the President's reception on Tuesday evening the Mayor and Mayoress received members of the Association at the Castle on Wednesday evening, and the local division held a reception on Friday evening Many excursions to beautiful and interesting places were arranged, and opportunity was provided for inspecting the local factories by invitation of the firms

Exhibition of Instruments, Drugs, Foods, and Appliances

The usual exhibition was held from Monday, July 19th, to Friday, July 23rd, in the Victoria Halls where the space and lighting were adequate for the display of material, both novel and well-tried for the furtherance of medical practice in many directions. There were more than 80 stands of which an account will be given in a later issue

---

SECTION OF MEDICINE.

Wednesday, July 21st.

The first session of this Section was devoted to a discussion on

Some Recent Developments in our Knowledge of the Biliary Tract.

Dr **Frank Harwood Jacob**, the President, said that it was to be the privilege of the section to hear those who had done notable original work on the biliary tract discussing their own subject He asked Prof **E A Graham** (St. Louis, U S.A.), who had initiated cholecystography, to deliver his address

Prof **Graham** said that disorders of the gall-bladder affected a large proportion of adult humanity and probably constituted the most frequent organic cause of dyspeptic symptoms. Yet the known normal functions of this viscus were merely the regulation of pressure in the biliary system and the concentration of bile by the absorption of water Other functions had been suggested, but had remained unproven Sweet had shown that in some animals which do not possess gall-bladders and in animals in which the gall-bladder had been removed there were a large number of saccules projecting from the walls of the intra-hepatic bile-ducts These might compensate for the loss of the organ Apparently, then, the serious consequences of cholecystic disease were due to something else besides the disturbance of the functions of the gall-bladder.

Inflammatory changes in the liver were, he said, a constant accompaniment of cholecystitis. By removing a small piece of the liver during operations on the gall-bladder the speaker had been able to show that a pericholangitis was present in every case. Other workers had corroborated his findings Microscopic examination of gall-bladders removed at operation showed that in the earlier cases inflammatory change was more often found at the periphery than in the mucosa of the organ. The older theory that bacteria especially the typhoid bacillus, were brought to the liver by way of the portal vein secreted in the bile, and thence carried to the gall-bladder, presented numerous difficulties. It was not easy to infect the gall-bladder by introducing bacteria into the lumen unless at the same time the cystic duct or artery was tied or the mucosa injured Moreover, both Osler and Rolleston had shown that cholecystitis was rare in the acute stage of typhoid fever when bacilli might be supposed to be numerous in the bile Infection via the cystic artery had been suggested, but the lymphatic path was probably far more important There was a very extensive anastomosis between the lymphatics of the liver and the gall-bladder. The results of experiments supported the hypothesis of lymphatic infection. Further, recent work on paratyphoid showed that cholecystitis did not occur in this condition unless there were actual inflammatory lesions in the liver. This finding seemed to corroborate the speaker's view of the spreading of a pre-existing inflammation of the liver to the wall of the gall-bladder through the lymphatic vessels Inflammatory lesions of the portal system might easily set up a hepatitis which in turn was followed by cholecystitis. Clinicians had long been familiar with this sequel to such conditions as appendicitis, peptic ulcer, and typhoid fever. The reverse was also true, for hepatitis followed experimentally produced cholecystitis A vicious circle could thus be established, each organ reinfecting the other. Kodama's work on lymphatics showed that a duodenal ulcer might directly infect the gall-bladder. In these cases the accompanying hepatitis would be secondary.

Prof Graham then described the investigations which led to his method of rendering the gall-bladder opaque to X rays by means of injections of tetrabromophenolphthalein, tetra-iodophenolphthalein, and its isomer phenoltetra-iodophthalein These substances were excreted via the liver into the bile They passed into the gall-bladder, where they were concentrated by the absorption of water. Hence the densest shadows were found in normal subjects. There would be no shadow, or only a faint one if the liver were unable to excrete the substance normally, if the cystic duct were occluded, or if the gall-bladder were unable to concentrate its contents because of a diseased wall. Cholecystography was really a means of studying the function of the gall-bladder rather than an indication of the exact pathological lesions present. But since from the days of Galen *functio læsa* had been recognised as one of the cardinal signs of inflammation, this condition, even in its early stages, could be detected by the method

The points relied on, he said, in making a diagnosis of cholecystic disease were: (1) Failure to obtain a shadow when the technique had been properly carried out (2) Filling defects Soft calculi were frequently seen as 'negative" shadows or filling defects Many small stones produced a characteristic mottled appearance. (3) Irregularities of contour, denoting adhesions, diverticula &c (4) Variations from the normal in density of shadow and in time of appearance and disappearance of shadow. These last were more difficult to interpret Out of 1144 cases examined by medicine and rather with politics It had been legally stated that it was ultra vires to attach any such condition Dr J A MACDONALD, seconding, said that it was not desirable to put a restriction on any man Dr E W MASTERMAN said that recently certain boards of guardians had tried to force all their employees, including doctors and nurses, into a trades-union After some trouble the compromise referred to in the motion had been reached, and it would be most undesirable to disturb it Sir ROBERT BOLAM said that the matter had been fully discussed by the Council, they did not wish and had never made any attempt to compel men to enter their own or any organisation, yet it would be the height of folly to refuse what was thus freely offered from an outside body, so long as it did not conflict with their policy or militate against professional integrity It had nothing to do with a trades-union

The motion was rejected by a large majority

Sir EWEN MACLEAN, proposing the adoption of the annual report under "Causation of Puerperal Morbidity and Mortality," mentioned the interim report and questionnaire which had been sent to the divisions, over 100 of which had returned careful answers

Poor-law Reform

Dr BRACKENBURY proposed the adoption of the report under "Poor-law Reform" which had been discussed earlier, and announced that a letter had been received from the Minister of Health stating that steps were being taken to protect the interests of medical officers at present holding appointments under boards of guardians A motion by St Helens and Warrington dealing with this point was therefore withdrawn

The Services

Sir RICHARD LUCE, Chairman of the Naval and Military Committee, proposed the adoption of the annual report under this title, and also

> That the Association expresses its satisfaction with the new rates of pay and conditions of service for the R A M C, and is prepared to assist the War Office in every way in its power to obtain an adequate number of candidates for entry into the Corps

He remarked that it had been promised that time put in as house physician or house surgeon should be allowed to count towards seniority, so that it would no longer be necessary for R A M C candidates to decide on their career immediately on qualification

Dr GOODBODY drew attention to the fact that in the Civil Constabulary civilian medical practitioners had been awarded higher rates of pay than Territorial officers Sir RICHARD LUCE replied that a letter had been received giving assurance that such an anomaly should not occur again if a similar force were called into being Dr GOODBODY said that, as such satisfactory terms had been reached, he would merely move formally a motion by Marylebone

> That the Representative Body, anxious to express its appreciation of the work of the Naval and Military Committee, assures the Council of its support in any further action which it may deem necessary to secure a just recognition of the reasonable claims of officers serving with the forces

This was passed

Sir ROBERT BOLAM expressed appreciation of the amount of time, patience, and strenuous work that Sir Richard Luce had given in helping to arrive at these very satisfactory results

Medical Charities

Dr J F WALKER, proposing the adoption of the annual report under "Medical Benevolence," made a strenuous appeal for a wide support of the Charities Fund, and stressed the very great importance of the work of divisions and branches and of panel committees The honour of the profession and the prestige of the Association were at stake There was no other profession that did not look after its distressed brethren, and there was no doubt whatever that many medical men were being broken in body and spirit through undeserved misfortune—some had been advised to apply for the old age pension—and that there was real distress among them and their dependents which it was the duty of the profession to relieve A subscription of £1 a year from every doctor would be sufficient

Overseas Branches

Sir JENNER VERRALL, proposing the adoption of the annual report under "Oversea Branches," referred to the negotiations with the Colonial Office about conditions of service in East Africa and Kenya, and said that the Office now realised that the Association was anxious to help and not to obstruct them, and to ensure that men entering the Colonial Service should know exactly to what they had to look forward

In addition to the further reports on Scotland, Ireland, and Wales, and formal business, a resolution of condolence was sent to Dr E M Cowell, who had come to Nottingham to represent Croydon, but had spent the week in hospital

Dr T W H Garstang was elected an additional vice-president, in recognition of his long and faithful service to the Association

ANNUAL GENERAL MEETING

The annual general meeting of the Association was held in the Mechanics' Hall, Nottingham, at 2 P M, on Tuesday, July 20th, when the outgoing President, Dr F G Thomson, inducted Mr R G Hogarth as President for the ensuing year The meeting received the report of the Representative Body that Prof Sir Robert Philip had been elected President for the year 1927–28 Sir Robert Philip welcomed the Association to Edinburgh for its annual meeting in 1927, referring to the Lister centenary celebrations with which the visit would coincide Sir Robert Bolam, in proposing a vote of thanks to the retiring President, said how greatly the Association regretted the illness which had deprived them of his presence on the occasion of the Bath meeting The meeting adjourned until 8 P M at the Albert Hall, where the Overseas Delegates were presented to the President by the honorary local secretary, and the gold medal of the Association was bestowed, amidst applause, on Sir Humphry Davy Rolleston, in recognition of his distinguished services to science, the profession, and the Association The first Sir Charles Hastings clinical prize was presented to Dr Norman Porritt, of Llandudno Mr Hogarth then delivered the presidential address which appeared in full in our columns last week

ANNUAL DINNER

The annual dinner, held on the evening of Thursday, July 22nd, at the Palais de Danse, was very largely attended Mr R G Hogarth, who presided, was supported by the Duke of Portland (Lord-Lieutenant) with the Duchess, the Mayor and Mayoress of Nottingham, the Hon Lady Birkin, Mr J Boot, and Mr F Acton In proposing "The British Medical Association" the Duke of Portland paid a tribute to the illuminating presidential address of Mr Hogarth, whom he described as one of the most eminent, most skilful, and most useful citizens of Nottingham He welcomed the Association to Nottingham with the opportunity it afforded to practitioners of learning the latest advances in medicine and handing them on to their patients, he voiced his appreciation of the value of a corporate body in medicine capable of expressing medical opinion to the public and to Parliament, and he announced the opening of a local branch of the British Empire Cancer Campaign, of whose committee he was president Sir Robert Bolam expressed his pride and pleasure at responding for the Association He wished success to the soon-to-be-inaugurated University of Nottingham and reported a year of smooth passage in the affairs of the Association, thanks to the unceasing diligence and toil of its voluntary workers He announced that future meetings of the Association were to be held at Edinburgh (1927), Cardiff (1928), Manchester (1929), and Winnipeg (1930)—in the latter case with a view of binding the ties of Empire He welcomed the effort to make this country accessible for post-graduate work acids and salts either in plasma or in bile In spite of much hard work the speaker had been able to find no way of doing so Obviously variations in these substances must alter the physics of bile and this might furnish the key to many diseases Only one fact about them was known—bile-acids were one of the first substances to cease to be excreted in obstructive jaundice

Cholesterol was then considered According to Naunyn the cholesterol in the bile was secreted by the wall of the gall-bladder, but every other observer was against this view Cholesterol in plasma and bile was derived from the cholesterol esters of the food Its metabolism was extremely conservative It was de-esterised in the liver, excreted in the bile into the intestine, where it was again esterised and reabsorbed This doctrine was founded on a considerable series of experiments, but was in contradiction to the French view According to the French the suprarenal cortex and the corpus luteum of the ovary were the producers of cholesterol in the blood In point of fact, however, these organs only acted as depôts Anything which raised the cholesterol content of the plasma raised the cholesterol in these situations or vice versa

With regard to diagnosis the mere presence of organisms in the bile was insufficient evidence for a diagnosis of cholecystitis Cholecystitis was an inflammation of the wall of the gall-bladder Graham's work on the lymphatic path and on the connexion between cholecystitis and hepatitis was extremely important In inflammatory conditions dead cells, cholesterol crystals, inflammatory exudate, and especially calcium salts were found in the bile Attention to diet was an important means of treatment, but it was useless to think that by withholding cholesterol the formation of stones could be prevented Its metabolism, as already explained, was too conservative to enable us to cut the substance out by dietetic measures Since sugar increased the excretion of bile-pigment and since glycogen protected the liver cells from a great variety of poisons, Dr McNee recommended the use of sugar in treatment

The speaker asked Prof Graham whether "bad arms" had followed intravenous injections of his drug

Dr T Izod Bennett said that the practitioner encountered many exceptions to the text-book pictures of gall-bladder disease The range of symptoms was very wide, tenderness to pressure below the right costal margin, when the patient was in the upright position, was the most constant sign Cholecystography had opened up a new phase in diagnosis The results in his experience were most satisfactory He employed the oral method exclusively It avoided "bad arms" due to thrombo-phlebitis in the vein In some instances variations in gastric and duodenal secretions had caused trouble in absorption, but if cholecystography was to come into general use the substance must be easily given without risk of local trouble The method enabled us to watch the progress of a case under medical treatment Dr Graham had done more than any surgeon to save patients from needless operation In treatment the speaker insisted on the necessity for water in abundance Egg-yolk also promoted biliary drainage The drugs he used were magnesium sulphate, bile-salts, and hexamine

Dr J H Anderson analysed a series of 50 cases and showed radiograms At first he had used intravenous injections, but he had given them up in favour of the oral method He had had no alarming after-effects In every case save one the X ray diagnosis had been confirmed at operation

Sir Berkeley Moynihan said that in a long series of cases diagnosis by cholecystography had proved accurate in 92 per cent Its value to the clinician was great, but greater still was the help it gave in determining physiological data Infections of the gall-bladder began outside, as a rule, and reached the inner surface later All gall-bladders showing adhesions should be removed Sir Berkeley Moynihan differed somewhat from Dr Graham in his opinion of the value of estimating cholesterol in the blood In the early stages of cholecystitis he had found a cholesterinæmia in a high proportion of cases The cholesterol in the bile was also increased, leading to the "strawberry" gall-bladder

Sir Humphry Rolleston said that he could not agree with Dr Hurst that we could hope with improved early diagnosis and treatment to do without surgeons. He had long used hexamine in gall-bladder disease. It gave relief, but he could not promise cure Early diagnosis was difficult because very considerable lesions often occurred without corresponding symptoms

Prof Graham, in reply, said that this morning's symposium had been one of the most interesting to which he had listened In answer to the question about "bad arms" he had had occasional cases of thrombo-phlebitis, but with improvement in the drugs used he hoped to do away altogether with this complication He was now using a new substance, and so far had had no local trouble with it.

SECTION OF MEDICAL SOCIOLOGY

Friday, July 23rd

Occupational Fatigue and Monotony

Dr C J Bond, the President, in his opening address at the morning session, said that, owing to the increasing stress of modern industrial life, the questions of the effect of fatigue and monotonous work were becoming of increasing importance, so that it was most desirable to enlist the interest of the whole medical profession in the advances recently made in this field of industrial physiology and psychology The meeting of this section, being open to the portion of the lay public interested in industrial health and welfare work, presented an excellent opportunity of hearing the views of representatives of the Industrial Fatigue Research Board and the National Institute of Industrial Psychology, of medical officers of large industrial undertakings of employers of labour, of welfare workers, and of the workers themselves Two principles must be kept in mind, if they were to build on a sound foundation (1) Every normal human being strives to obtain some sense of satisfaction from energy expended and work done, and failing such acquirement, effort becomes reduced in volume or is diverted into other channels It was just as important to raise the standard of life in the factory and workshop as in the home If workers derived real satisfaction from their daily work there would be less unrest in industry (2) The second principle was concerned with finding the right man for the job—vocational selection. The industrial problem was an evolutionary one, and the worker must be fitted by nature or by training for his particular occupation and become adapted to his industrial environment

Mr A Hudson Davies, of the National Institute of Industrial Psychology, opened a discussion on the

Monotony Factor

He gave the University boat race as an illustration of monotonous work. The effect of monotony was felt in the training, but not in the race, owing to the incentive A muscle exhausted by repeated contractions would still contract under electrical stimulation. Industry was becoming specialised and repetitive work was the result—the same effort repeated every few seconds with uniformity and no surprises for the worker and no variety so as not to waste a man's special skill The effect varied with the worker There was a perpetual holding by the worker of himself in check, but no freedom for reveries Workers of good education and intellect employed at, say, a monotonous counting job, might feel resentment that their full powers were not being called out, and gradually become conscious of a hampering of intelligence and of inertia Others might develop curious mental symptoms, indulge in day-dreams with a feeling of guiltiness and even fancy they were being watched or going mad Sometimes the irritability or resentment of the worker found relief in spoiling material It was most important to counter all the cholecystography 128 had their gall-bladder removed at operation. The pathological examination confirmed the X ray diagnosis in 124. Toxic reactions occurred in a certain number of cases after intravenous injection and more after oral administration of the drug, but they were seldom severe. No death had been recorded following the injections.

Besides its clinical application cholecystography had been made use of in the study of the physiology of the gall-bladder. Prof. Graham's own findings and those of his co-workers threw considerable doubt on Meltzer's hypothesis of a reciprocal innervation of the sphincter of Oddi. The gall-bladder contained but little muscle. In spite of prolonged observation the speaker had never seen peristaltic contractions. The viscus emptied itself by a gradual washing out following the inflow of fresh bile and by elastic recoil. Increased abdominal pressure also played a part. The muscular coat of the duodenum was an important factor in regulating the outflow of bile. The common duct passed obliquely through the duodenal wall for 2 or 3 cm., so that peristaltic contractions had a milking action on it. Substances supposed to have a specific effect in emptying the gall-bladder probably did so by stimulating duodenal peristalsis.

The speaker illustrated his points by a series of remarkable X ray pictures.

Diagnostic Considerations

Dr. A. F. **Hurst** said that gall-stones were found post mortem in 10 per cent. of cases after the age of 20. Their formation was always preceded by cholecystitis, but many people who had attacks of cholecystitis did not develop gall-stones. A large part of the population suffered at one time or another from the disease. Therefore cholecystitis was not only, as Prof. Graham had said, the commonest organic, but the commonest of all abdominal diseases. Text-books gave much space to the rarer and more serious lesions of the gall-bladder such as empyema or gangrene, but little to the more important because much commoner milder infective disturbances. The latter in the early stages were amenable to efficient medical treatment, and the formation of gall-stones could be prevented. It was important that practitioners should realise that cases of flatulent dyspepsia might really be cholecystitis. Sir Berkeley Moynihan had described the symptoms with great accuracy. The chief were tenderness in the region of the gall-bladder, spots of referred tenderness, and slight rigidity of the right rectus muscle. For accurate diagnosis, said Dr. Hurst, the patient should be sent to a team (a diagnostic team of this type should exist in every town) consisting of a radiologist, biochemist, bacteriologist, and clinician. A complete abdominal examination was necessary because cholecystitis was often associated with appendicitis, peptic ulcer, &c. Hyper- or achlor-hydria existed in 50 per cent. of the cases. The speaker considered that the information to be derived from the passage of a duodenal tube was as important as that obtained from cholecystography. Normal cholecystograms were sometimes found in patients in whom the duodenal tube gave evidence of disease. In cholecystitis the bile specimens withdrawn contained pus and epithelial cells, organisms (generally *B. coli*), and cholesterol crystals.

With regard to treatment, Dr. Hurst maintained that cholecystitis was an infective disease and the infection must be overcome. The biliary tracts could be sterilised by hexamine. Hexamine was not, as a rule, effective in alkaline secretions, but bile was an exception probably owing to lowered surface tension. If sufficient alkali was given with hexamine it did not act as a urinary irritant and could be administered in large doses. He frequently gave 100 gr. three times a day. This quantity acted as a powerful biliary antiseptic. Achlorhydria was a predisposing cause of biliary infection, and to patients showing this symptom he was in the habit of giving a drachm of dilute hydrochloric acid before meals. Hyperchlorhydria could be controlled by olive oil, which had the additional advantage, as Prof. Graham had shown, of causing a flow of bile into the duodenum and thus preventing biliary stasis.

Dr. F. A. **Knott** drew attention to some important points in connexion with the use of the Einhorn tube. He analysed a series of 71 cases of gall-bladder disease in which examinations had been made of bile from the duodenum. Out of 25 cases of gall-stones three gave normal reactions. In the others the bile contained crystals and bacilli. In 46 cases without calculi the bile gave normal reactions in 26 per cent. 40 per cent. of cases showed achlorhydria. He thought that the action of urotropine might be due to the acid produced by the organisms. *B. coli* might ring themselves round with acid and formaldehyde might thus be liberated in their neighbourhood. Lowered surface tension also was inimical to the growth of bacteria.

Prof. D. P. D. **Wilkie** expressed his satisfaction at finding cholecystography so widely practised. It was an extremely valuable aid to diagnosis and should become a standard method. His experience was in conformity with Prof. Graham's statement that the intravenous method gave the most accurate results. Very great care in technique was necessary to prevent reactions. He found that males were more immune from reaction than females, perhaps because the male was more immune to cholecystitis than the female. Dr. Wilkie spoke of the value of physiological research into the functions of the gall-bladder and remarked that the exalted egoism of the sphincter of Oddi had been rudely shaken by Prof. Graham and his co-workers. Dr. Hurst and Dr. Knott had stated that primary infection of the gall-bladder was the origin of all stones, but a single cholesterin stone might form aseptically. He had grown streptococci from the wall of the gall-bladder in cases where the bile itself was sterile. From this it followed that the presence of disease could not always be proved by the Einhorn tube, nor could it necessarily be cured by drugs excreted into the bile.

Mr. C. F. W. **Illingworth** gave his experience of cholecystography. He had followed Prof. Graham's technique and preferred intravenous administration of the drug. In 111 cases which came to operation the X ray diagnosis was confirmed in all but 12. In his hands the method had been of no value in obstructive jaundice, but was of great assistance in the differential diagnosis of palpable abdominal tumours. His paper was illustrated by beautiful X ray plates.

Alterations in Biliary Secretion under Different Conditions

Dr. J. W. **McNee** dealt with the alterations occurring in the biliary secretion under different conditions. Normally the chief constituents were water, bilirubin, bile-acids and salts, and cholesterol. In disease additional substances were found, the most important being calcium salts. Bile as secreted differed from that found in the gall-bladder, principally owing to the absorption of water by this viscus. In animals gall-bladder bile was ten times as concentrated as that found in the biliary passages. Only two functions of the gall-bladder were known, but it must have others besides. It was ridiculous to regard it as a rudimentary organ just because surgeons could remove it. Speaking of changes in the bile-pigment the speaker said that bilirubin was derived from hæmoglobin from which the iron-containing particle had been split off. Therefore it might seem that the amount of bilirubin must depend on the amount of hæmoglobin broken up—i.e., on blood destruction. In favour of this was the fact that in acholuric jaundice pigment stones were frequent. On the other hand, Whipple and Hooper found no increase in bile excretion after large injections of hæmoglobin. The effect of increased blood destruction appeared very variable. Diet, however, might considerably modify the pigment excretion. In dogs on a mixed diet there was little variation, but if sugar or carbohydrate were given the pigment excretion was considerably increased and remained so for some hours. Meat, on the contrary, led to a diminution in excretion. It was unsatisfactory that no accurate method existed of determining bile-labour, and machinery must be studied from the point of view of the comfort and convenience of the workers Mr Hichens went on to refer to the work of Taylor and the Gilbreths in America In that country the workers took more interest in scientific management and time and motion study, and the trade unions helped by appointing their own investigators But research work of the kind necessitated was slow and had to be continued over long periods Workers must be got to appreciate that posture and change of posture were important. Local fatigue of muscles might be alleviated by bringing in other groups of muscles Rest pauses were important Hours of labour had unfortunately become a political question and were not studied scientifically Temperature affected output, which was greatest in winter In hot mines the output was lower than in cooler Amongst other matters needing study were the incidence of sickness, the proper lighting of factories with the prevention of eye-strain, the provision of baths, vocational selection and guidance, and the liability to accident The Government, employers, and workers must encourage the Board and secure research on a bigger scale

Dr H M VERNON investigator for the Board, followed with a paper, illustrated by lantern slides, dealing chiefly with workers engaged on strenuous work at high temperatures in the tinplate industry, in steel melting on open-hearth furnaces, and in coal-mines His slides showed graphically how the output decreased in the hotter months of the year and how very greatly this decrease was lessened by good ventilation and attention to cooling If the ventilation and cooling were not adequate, he showed the fatigue induced caused excess of sickness, chiefly displayed in rheumatism and respiratory diseases. Regulations for rest pauses were possible in light repetitive work, but not in this heavy work. In some cases the rests were taken with regularity, but the coal-miners took their rests irregularly

In closing the Section the PRESIDENT made reference to telegraphists' cramp and the value of counter-action by bringing into play other groups of muscles He laid special emphasis on the valuable results which would accrue from attention to vocational selection

Reviews and Notices of Books.

RADIOLOGY

Radiotherapy in Relation to General Medicine By FRANCIS HERNAMAN-JOHNSON, M D Aberd Oxford Medical Publications London Oxford University Press 1926 Pp 211 5s

THIS small handbook, directed to the general practitioner who wishes to know something of the theory and application of radiotherapeutics, is written by one who has great and wide experience of the subject Since the advent of the intensive methods of X ray treatment the complexities of the mechanism and mathematics have overshadowed the medical aspects of the subject As Dr Hernaman-Johnson puts it "the radiotherapeutist has in the past of necessity been over much preoccupied with the technique of his art", the author attempts to write as a physician practising radiology The result is not a text-book, but a common-sense, individualistic, and readable exposition of the present position of radiotherapeutics in relation to general medicine It is obvious that the writer has taken pleasure in setting forth his views unhampered by the technicalities of his subject The short chapter on the essential elements of the physics of radiation has the visé of Dr G W C Kaye, of the National Physical Laboratory, in the chapters on the effects of radiation on the normal cells and the nature of disease, Dr Hernaman-Johnson has the support of Dr Mottram, the Director of Research of the Radium Institute, Prof Russ, of the Middlesex Hospital, has read through Chapter IV with a view to securing accuracy as to the references to animal experiments in relation to cancer

The rest of the book is a well-reasoned statement of the author's own practice in relation to the treatment of cancer in various regions, in pelvic conditions such as uterine fibromata, in hyperthyroidism, affection of the ductless glands, tuberculous glands, and many other diseases The treatment of superficial conditions receives only passing reference Of deep therapy, as enunciated by the Erlangen school, the author states that it is quite unsuccessful in the treatment of the hopeless cases of cancer as we see them, but he is prepared to believe that these intensive methods may be of value for early cancer of the uterus, a condition which is rarely passed over to the radiologist in this country He holds that this particular technique for deep therapy should only be employed for comparatively small circumscribed areas, the constitutional reaction from the treatment of large areas making the procedure unjustifiable Obviously, deep therapy has a definite place in medical treatment, particularly of cancer, but the kill or cure method of using it as laid down by the Erlangen school should be replaced, the author holds, by a much less drastic technique, the big doses being divided over several days

We can strongly recommend this small volume as a clear statement of the medical side of radiotherapeutics

---

The Technique of Oral Radiology By CLARENCE O SIMPSON, M D, D D S, F A C D. St Louis, Mo London Henry Kimpton 1926 Pp 207 21s.

THE use of X rays in dentistry has progressed very rapidly since the days, not so long ago, when specially prepared dental films first became available, days when dark-room assistants cut and wrapped pieces of X ray plates or ordinary photographic films for each exposure In this volume we have a book of 200 pages entirely devoted to the consideration of this one branch of radiology With 165 illustrations and a clearly expressed text, the technique is explained simply and clearly, and in a way that should be useful, particularly to those who have not expert knowledge, even for those who are experienced there are many tips which will prove useful We would specially commend the chapter on Systematic Procedure as being concise and most helpful It is interesting to note that the author uses an ordinary X ray tube stand for this work and not one of those specially designed for dental purposes The last chapter is devoted to a wise discussion of protection from the dangers of X rays, and, if the author's recommendations are carried out, the operator should not receive any radiations which will do him damage

Those interested in dental radiography will learn much from this work

---

INSTINCT A STUDY IN SOCIAL PSYCHOLOGY By L L BERNARD, Professor of Social Psychology, University of Minnesota London George Allen and Unwin Pp 550 15s

THE aim of this book is to show the fallacies supposed to underlie current conceptions of instinct The word is so widely and loosely used that attack is easy, but the argument centres on McDougall's well-known work, which attempted to build up a social psychology on the basis of instincts common to man and the lower animals The author regards instincts as reflexes or action patterns which in man are mostly vestigial and so disintegrated by the encroachment of habit that the theory of instinctive control is valueless when applied to sociology Yet he concludes that "The real task is to discover the mechanisms by means of which the child and the citizen build up their habits upon the basis of the instincts, directly or indirectly, and by means of which one habit or set of habits is transformed into another" This is a fair expression of the aim of possible effect of monotonous work by attractive environment in the factory and by outside recreation

Miss May Smith (Industrial Fatigue Research Board) said the complaints of monotony generally came from highly educated observers, who judged how the work would affect themselves Observers must learn to see the work as it really appeared to the worker They need not concern themselves about people who desired monotonous work, but only with those who were forced or drifted into it Among the latter some of the reactions to monotonous work were boredom, excuses for escape from work, resentment of correction, tiredness complaints of pain, nervous dyspepsia, lessened resistance to colds or influenza, and loss of interest leading to nervous breakdowns Some got relief from day-dreams, others had unpleasant day-dreams and became psycho-neurotics Others made bitter complaints against the monotony, while some laughed at monotony, and she had known such an event as the preparations for a fancy dress dance temporarily relieve the situation

Major T. Knowles (supervisor, Boots' welfare centre) made a spirited defence of repetitive work and claimed that the girls employed on it were both healthy and happy The work was easy and not nerve-wearing, and the workers got their opportunities for recreation and self-development in their leisure Science had given them machines, and machines necessitated repetitive work with much less physical effort on the part of the operative He would like to encourage the love of machines Those who condemned repetitive work had nothing to offer in its place The girls engaged in repetitive work to a large extent made up the evening classes in commercial and domestic subjects, and resented any effort to have their work changed The percentage of sickness among them was about half that of the other workers They played their part in social, educational, and recreational developments But he would only plead "not guilty" on the monotony question, for the employer *if* he had taken every precaution, had observed time-shifts and studied movements, and provided proper ventilation, rest pauses, and suitable apparatus to ensure safe and easy working He believed that industrial welfare was the expression of industrial conscience, willing and anxious to uplift our factories and warehouses and bring business to a grand conception of its duties to those it employs, and to the public at large And, in connexion with the welfare work at their own factories, he desired to pay tribute to the local medical practitioners for their coöperation

Miss Slocock (H M Inspector of Factories, Leicester) said the reaction to monotony was a matter of temperament One of the troubles in modern industry was the loss of the creative sense, because the worker did not see the finished work as a rule In this respect weavers had an advantage, which accounted for that work being popular With repetitive work had come shorter hours, and to-day under modern conditions the workers appeared to be brighter and more alert even when performing monotonous jobs Monotony could hardly be considered alone, and there was no agreement as to the adverse effect on health of repetitive work A good environment, good working conditions, and a friendly atmosphere in the factory were more important

Miss K Dowding (Chiswick Polish Co, Ltd) thought very little monotony was felt by girls in well-organised factories, but some girls were constitutionally or emotionally unfitted either for working on machines or at piece-work. Return to craftsmanship was impossible and the modern girl disliked the solitary spinning-wheel Love of machines was not now a male perquisite only The placing of operatives suitably was being more and more attempted, for it was realised that one discontented worker might affect a whole group and spoil the output The feeling of being absorbed into a vast impersonal soulless mechanism had to be combated by recreations and the holding of individual positions in outside activities Girls were favourably influenced by working with their friends, even if they could not talk to them The personal element must not be ignored Monotony was not a problem by itself

Dr Stuart Mackintosh (Hampstead) discussed the subject from the racial and temperamental point of view

Dr J Jenkins Robb (Bourneville) thought the study of psychology in labour might easily be overdone The worker was suspicious of repetitive work because it increased profits more than wages The stress of modern industry affected all ranks of labour, including the highly paid jobs

Dr Leonard Lockhart (Boots' Pure Drug Co) uttered a warning against labelling vague ill-health as "neurasthenia" It was difficult to unstick the label He appealed for the cooperation of the general practitioners with the works doctors and for the recognition of the latter under the Insurance Act

Dr Christine Murrell said the highly educated worker should be kept out of monotonous and unintellectual tasks by vocational tests

Dr C Forbes (Aberdeen) pointed out that instruction in industrial medicine was needed for insurance practitioners

Sir Thomas Legge (Chief Inspector of Factories) reviewed the history of the guilds with their care for the sick, their efforts to promote good work and pride and joy in the work, and their strict regulations, designed to foster these aims The guilds supplied people with what they ought to want, not with what they might think they wanted Welfare work was now bringing back "the interest in the job" lost during the industrial revolution of the last century Monotony had not come much before him and took a back seat in comparison with the removal of gross defects in environment

Dr H B Brackenbury said monotony was not merely repetition The mental effects of monotony might need to be dealt with without waiting for environment to be made perfect The pride in the finished product might be replaced in various ways The finished article should be brought to the notice of all who had had a hand in turning it out, so as to stimulate communal pride in the team work and the life of the factory Better education in art, such as they were getting in their schools, would stimulate artistic pride in the factory and the articles it produced To many people their leisure was more monotonous than their work Attention to recreations and activities outside the work of the factory would help to bring about a proper attitude towards life

At the afternoon session the Section discussed the

Physical Fatigue Factor

Mr W L Hichens (chairman of Cammell, Laird and Co), a member of the Industrial Fatigue Research Board from the early days, opened the debate on this subject The reproach, he said, that industry in this country had not made enough use of science was probably true, and they certainly had not given enough attention to the human factor It was not enough for employers to want to make their workers healthy and wealthy, they needed to make them contented, and contentment did not come from mere health and wealth, but from the knowledge that the conditions under which a man's living was being earned were the best possible, and that every consideration was being paid to him as a human being The name of the Industrial Fatigue Research Board was perhaps unfortunate, but it had done good work, and could do much more But the Board needed encouragement not only financially They wanted more interest taken in their work and to have a wider sphere of influence No industries nowadays involved serious injurious fatigue to normal workers in good training Nature made a man go slower when fatigue began to operate During the war the special effort and the longer hours affected the work, but did not damage appreciably the health of the workers Shorter hours brought better work. Fatigue in strenuous work might be a predisposing cause to disease So far as possible all unnecessary effort must be saved by the substitution of machines for hand-

for recruiting or retaining in the care of the ntally sick those with a real gift for mental ursing, even if unable to pass the examination tandard for general nursing

In regard to the fear, largely responsible for the nquiry, that under the present system there has been a risk of wrongful certification and a lack of kindness and consideration in treatment the Commissioners are able fully to reassure the public, for they state that instances of sane persons being certified as insane are of the rarest occurrence and that, although isolated instances of cruelty have occurred, there is no foundation for the suggestion that ill-usage has been deliberately or systematically practised At the same time they point out that, while the public must be safeguarded against the presence in their midst of persons of unbalanced mind and dangerous tendencies, the reluctance is inevitable of medical practitioners, in the present state of lunacy law, to be involved in the certification of the insane, owing to the risk of legal proceedings They therefore propose that doctors shall not be liable to be proceeded against in a civil or criminal court unless they have acted in bad faith or without reasonable care, and that any such proceedings against them should be stayed by summary application unless the court is satisfied of wrongful motive or neglect of precaution The Commissioners accept the need for the existence as a separate organisation of a Board of Control, subject, however, to general control in matters of policy by the Minister of Health, but they think that the Board should be reorganised so as to consist of a small headquarters staff of four or five Commissioners, assisted by a much larger visiting staff of Assistant Commissioners Every facility is to be given for making the public familiar with the inside of the mental hospital by means of voluntary unofficial visitors of suitable experience to be appointed by the authorities of every institution, liberty being given to visiting committees to coöpt suitable persons who are not members of the local authority, at least two of whom should be women

The Report is a bold though temperate acknowledgment that the existing lunacy administration has not kept pace with increasing sociological experience, and especially has not evolved in proportion to a vast modern growth of medical knowledge both general and in the field of medical psychology Yet some of the suggested methods of reform have already been adopted by enlightened mental hospitals Many others would now be in working had it not been for financial difficulties which have become more acute n recent years Most of them have been recommended or long by the Medico-Psychological Association It will be no small relief and satisfaction to the mental ospital service if measures which have so far been ardly achieved by constant pressure and scrupulous conomy now become statutory duties The early reatment of mental disease without certification has ready made a beginning in various places in spite of gal hindrance, and the recommendations of the mmission as a whole will have the solid support the medical profession But early treatment and dance of detention under certificate can only be ved when an intimate knowledge of the first toms of mental disorder becomes the common sion of the whole medical profession, and we all attention again to our issue of a Special ent on Early Mental Disease, written by those hority and knowledge expressly to meet this The Supplement appears simultaneously eport of the Commission

A Necessity in The Hospital The Nursing Home The Sick Room

McDougall's "Social Psychology," but from occasional references to his opponents' views as mystical or metaphysical one judges that the real point of difference is that Prof Bernard is one of those who dislike the psychology that pries into human motives In the endeavour to escape such a psychology he is driven to use curious conceptions, as when he writes (p. 466): "The activity attitude, or even the organisation of the neural processes along the lines of thought, cannot be immediately repressed or undone" This goes beyond the world of physics and would be scorned by metaphysicians, perhaps it might be described as paraphysics

The theory of instincts is far from satisfying and may undergo many changes or ultimately be cast aside, but it serves too useful a purpose to be relinquished as a result of purely destructive criticism

---

DISEASES OF THE KIDNEY

Pathologie und Klinik der Nierenerkrankungen
Second edition By Prof FRITZ MUNK Vienna: Urban and Schwarzenberg 1925 Pp 661 M 25 50

THIS important treatise is the second edition of Prof Munk's well-known work on Bright's disease and kindred disorders There is no reference book in English which deals with the subject so broadly and at the same time in such detail, and since the first edition has been out of print for some years its successor has been eagerly looked for The first 150 pages deal with the physiology of renal secretion, the urine in health and disease, and functional efficiency tests The rest of the book is concerned with Bright's disease in its various forms The author divides Bright's disease into the three main categories of Nephrosis, Glomerulo-nephritis, and Interstitial Nephritis as a manifestation of Essential Hypertension

As an original contribution to medical literature the section dealing with nephrosis is the most important because, although Volhard is responsible for naming the group of renal conditions which are included under this term, it was Prof Munk who first made the distinction for clinical purposes between lesions which are initially or primarily degenerative and those which are definitely inflammatory The distinction is largely made on a pathological basis, but the author maintains the distinction clinically, and he takes syphilis of the kidney as the classical example of nephrosis, he speaks of the syphilitic virus as the cause of typical pure lipoid-nephrosis, using the term in both a pathological and clinical sense A discussion of the term "nephrosis" and the meaning given to it will be found in a short introductory chapter (pp 173–184) preceding the detailed discussion of Bright's disease, and again in the sections describing lipoid-nephrosis In the rest of this chapter there is a good deal of perhaps unavoidable repetition The chapter on nephritis (pp 365–496) is chiefly concerned with glomerulo-nephritis, and the main feature of the author's presentation of this section is his insistence on the now generally accepted view (which he has held for many years) that nephritis is a general disease in which the kidneys are chiefly affected The account on p 405 of cases of Bright's disease in which there was no albuminuria or cylindruria is interesting in this connexion The last chapter deals with Interstitial Nephritis as a manifestation of Essential Hypertension These terms are so open to alternative construction that the actual phrase used in the text may be given "genuine Schrumpfniere" als Teilerscheinung der "genuinen Hypertonie" (author's inverted commas) The view is put forward that anatomically interstitial nephritis is really a disease of the blood vessels, in contradistinction to the older view that it is primarily a disease of the kidneys

It will be evident from this brief survey that Prof Munk presents each of his three main subjects as a thesis Nephrosis is characterised by its being a degenerative as opposed to an inflammatory change in tissue structure, glomerulo-nephritis is a disease of the whole body, interstitial nephritis classed with essential hypertension (there is no reference to the late Sir Clifford Allbutt's work) is a disease of the blood vessels Bright's disease as a name for the whole group finds no other term to replace it, and yet as a disease of the kidneys *ueberhaupt* it may seem to the reader of this treatise that it ceases to exist

---

EDWARD THRING MAKER OF UPPINGHAM SCHOOL

By W F RAWNSLEY. London Kegan Paul, Trench, Trubner and Co, Ltd 1926 Pp 103. 3s 6d

THE life of a great schoolmaster is a medical subject, and no great schoolmaster ever realised more acutely than Edward Thring the value of education in its bearing upon the wholesomeness of the future career That the body should be as keen and alert as the mind was the inspiration of his work, as it is the physician's ideal

Thring's biography has already been written by Sir George Parkin, the organising secretary of the Rhodes Scholarship Trust, and a keen enthusiast for progressive education Parkin was a profound admirer of Thring, but he knew him personally hardly at all, and had to rely on diaries for the more intimate details of his subject When the biography appeared it was not felt to be an adequate picture, it contained Thring's meditations on many of the obstacles that beset him as a reformer, but did not convey the intensely human and active side of his life Mr Rawnsley, the son of Thring's friend, a pupil at the dawn of the transformation of the local grammar school into a leading public school, and later a house-master at Uppingham, draws a vivid picture of the great little man who for thirty-four years was the hero and terror of his charges his strenuous devotion to duty and his power of putting his heart into holiday-making, his merriment and his causticity are faithfully recalled

Thring's father was a Somersetshire squarson, and his mother a descendant of seven generations of clergymen, he was born at a time when educational methods were based on severity and characterised by absence of sympathy Many medical men find that these methods are to-day over-reversed, and that they have to deal too often with physical troubles due to spoiling, but there is no doubt that in early Victorian days a rigorousness towards children survived that was alike an anachronism and a hurtful thing It was his memories of his early life that made Thring long to make the sojourn of boys at school a more human matter Not that he himself seems to have suffered personally at Eton, either as an Oppidan or a King's Scholar, he emerged as a distinguished classic, an adequate sportsman, and a happy man But he was profoundly humane, and he knew that many of his school friends had been miserable, and that it was no part of school life at that time to take note of such cases He took Holy Orders upon graduation, and in 1853 was offered the headmastership of Uppingham, an ancient grammar school which at the time was reduced to 25 boys His stipend was £150, and he had little personal means He must have accepted the post, primarily because he felt that he had what is often described slightingly as "*a call*" to the cause of education, for Thring was never in any doubt that he was doing work for God In the second place he entered upon his headmastership in the spirit of adventure He had theories and views upon education, and he wished to see them in practice He put them to the test and succeeded in increasing the number of boys to 300—beyond which figure he always refused to go for an upper school—and it is the story of this work which Mr Rawnsley tells very briefly but none the less thoroughly The flight of Uppingham to a Welsh fishing village during the resewering of the Rutlandshire town was a famous example of organisation, though the circumstances which brought about the migration are, fortunately, such as modern public health administration have made impossible matter with the poor is poverty' is not substantiated by these investigations, which show that the problem of a slum population is far more complex than such a statement would indicate."

Current teaching, they suggest, gives too much rather than too little, weight to the environmental factors which, theoretically at least, it might be possible to remedy by economic adjustment; in spite of conditions around him the slum child tends to develop on the lines of his parents. Both for its interesting conclusions and as a record of well-conceived investigation the report deserves wide circulation. It is a work of art, because it depicts elusive and complicated phenomena in words and figures, and to read it is an education in scientific method.

◆

THE B.M.A. MEETING AT NOTTINGHAM.

NOTTINGHAM was something of a surprise to the many hundreds of medical men and women gathered there last week at the ninety-fourth annual meeting of the British Medical Association. Although a very important industrial centre, and happily in most directions a prosperous one, the stigmata of industrialisation are scarcely to be observed in a city of cleanly aspect with pleasant undulations and large open spaces, and the casual visitor may remain unaware that there are several coal-mines within the municipal boundary and at least one hundred hosiery factories within the county, apart from the mass production of fine chemicals, tobacco, and cycles. Most of the meetings of the Association took place in the University College which, through the generosity of Nottingham's industrial magnates, is shortly to be removed to a new and admirable site where, it is hoped, a great North Midland University may soon come into being. Happily, the hospital buildings by successive enlargement have kept in touch with the increasing population and with the growing demands of scientific medicine, a new out-patient department with a magnificent central waiting-room is approaching completion, and when the time comes these buildings are fit to take their place on the clinical side of the medical school which need hardly wait long to appear after the grant of a charter to the University.

The sectional meetings covered a wide range of subjects, many of them of immediate practical interest to the general practitioner of medicine, and the Duke of PORTLAND was no doubt right in describing the meeting as a magnificent opportunity offered to general practitioners to learn the latest advances in medicine and to hand them on in turn to their patients. Several sections took on an international character in their discussions, notably the Section of Anæsthetics, which utilised the opportunity of a visit to Europe of a number of transatlantic anæsthetists, a joint meeting with the Section of Surgery being arranged to discuss the principles of anæsthesia in abdominal surgery as they have not previously been discussed in this country. While we have many excellent methods of anæsthesia, most of them fairly easy of application, and while the art of anæsthetisation is rising to the status of a science, it has still to be remembered that relaxation and quiet breathing, so essential to the abdominal surgeon, are not the only things to be kept in mind, for the patient is something more than an abdomen, and has a brain, a heart, kidneys, and a liver which may be impaired by the anæsthetic employed. Several American and continental delegates set out the practice of the newer gaseous combinations whose attractive novelty is not their only justification for employment as analgesic agents. In the Section of Medicine, one session of which we are able to report this week, a discussion on blood transfusion in the treatment of disease took on a wider scope from the presence of Prof. R. CRUCHET, of Bordeaux, and Prof. E. A. GRAHAM, of Toronto, while Prof. CARTER WOOD, of Colombia, communicated his experimental results with lead in the treatment of malignant neoplasia to a later session of the same section.

On the administrative side this year's Representative Body had no burning question to discuss. Dr. BRACKENBURY, as chairman of the Body, was able to report, with perhaps a twinge of regret from a practised controversialist, a year of smooth passage in the affairs of the Association. Only the Memorandum of evidence submitted to the Royal Commission on Local Government came in for some hostile criticism and was referred back to the Council for further consideration before action. All were agreed as to the principle of separating health services from other administrative services and then combining them first centrally and then locally under one form of administration, and agreed also on the impracticability of the ideal parcelling out of the country into fresh areas, each with a large town as centre; but the Medico-Political Committee of the Association, through its Chairman, voiced its disfavour of the proposal to give to county councils control of all health matters within the county even should it contain such a large borough as Willesden with its 200,000 inhabitants and its successful autonomous authority of long experience. There was some feeling in the Body that the proposals in the Memorandum might smooth the way for a State Medical Service, in spite of Dr. BRACKENBURY's categoric assurance that the extended employment of local practitioners in auxiliary services and clinics should act as a bulwark against a State service. In his admirable presidential address, which we published last week, Mr. HOGARTH championed the principle of voluntaryism, so triumphantly maintained in hospital practice, and stated the one urgent need of the Insurance Service to be the linking up of the insurance practitioner with the consultant physician and the consultant surgeon in order to give the insured patient the benefit of specialised as well as general medical knowledge. He also forecasted the rapid extension of the system of paying wards in hospitals. The key-note of his address was the consistent aim to raise the general standard of health among all ages of the community and especially among the adult workers. This aspect of health work was reflected in the remarkably interesting sessions of the Section of Medical Sociology which we also briefly report in this issue. The discussion was piquant for the frank line taken by speakers, both lay and medical, in denying the existence of harmful monotony in the life of factory operatives under proper conditions. One prominent welfare worker, indeed, challenged the right of those who chose such a sport as angling for their recreation to brand as monotonous any repetitive occupation. If only the work is done under healthy conditions and the worker has the opportunity of honest pride in the finished product, medicine can say little, it was urged, against routine occupation which leaves the worker free to develop his powers of body and mind in his leisure time. Most of the world's work is routine work, said Mr. HOGARTH in his address, and the conditions of factory life as observed in Nottingham during the visit of the British Medical Association no doubt gave many of its members the opportunity of reconsidering some of the almost prejudged questions of industrial fatigue. The meeting of the Association, although not outstanding in any one direction, was felt to be a thoroughly useful and instructive one.

POVERTY, NUTRITION, AND GROWTH

Current opinions on social problems are mostly based on small series of observations by individuals Nowadays, however, evidence is being collected on a larger scale Groups of investigators dealing statistically with great masses of material can form conclusions comparatively free from personal bias, and it is interesting to see how far research scientifically conducted really bears out the generalisations usually regarded as truths The first results of one such undertaking are now being published[1] After six years of work the Scottish Committee for Child Life Investigation, under the chairmanship of Prof Noël Paton, has produced a report so elaborate as to justify its exceptionally interesting conclusions The investigation is described as "the first extensive attempt to estimate the influence of various environmental conditions on the growth and nutrition of the slum child" It was carried out, under the general direction of Prof Paton and Prof Leonard Findlay, by a number of doctors, statisticians, and health visitors, and the data were collected in the poorer quarters of Edinburgh, Glasgow, and Dundee by means of house-to-house visits and with the help of child welfare centres In each of the towns over 93 per cent of the families investigated lived in one- or two-roomed houses, but care was taken that those selected should be as far as possible a random sample of the slum population For purposes of comparison investigations were also made into the condition of the children of miners and agricultural labourers in various parts of Scotland The whole formed part of a scheme for the study of child life which was initiated by the Medical Research Council, but unfortunately no similar work was carried out in England at the same time The report is valuable not only for its lucid description of this work done in Scotland since 1919, but also because it summarises carefully the conclusions of previous investigators Unfounded assumptions are absent, and this may explain why the evidence gives little support to numerous prevalent ideas

Many observers had previously shown that in great cities the children of the poor are lighter and smaller than those of the wealthy, and that they also compare unfavourably with those of their own social class who are reared in the country About 80 per cent of our national population are now town dwellers Emigration from the country has almost come to a standstill, the towns are breeding more and more their own populations, and there is some indication, says the report, that the small size of town children is in part at least an inborn characteristic A stunted population might conceivably be a result of the survival of those best fitted for town life Unfortunately no figures are available to show the relative weights and heights of town and country children at birth, either in Scotland or elsewhere, but the present inquiry suggests that there is some delay in the rate at which the town child grows between birth and the age of 18 months During this time there seems to be a lag in development, though afterwards growth goes on as rapidly in the town as in the country child; but the Scottish Committee has been unable to correlate the slowing of growth with any particular environmental factor chiefly operative before the middle of the second year of life The suggestion that town infants show this retardation because they do not get enough milk does not explain the facts, for the amount of milk consumed by the families of rural miners—who show no such retardation—is even smaller "Perhaps the most prevalent belief," say the Committee, "is that the small size of the town child is due to a defective supply of suitable food, but the satisfactory rate of growth after 18 months does not support this view" In a certain number of cases in which it was possible to correlate the energy value of the food with the weight of the children, it was found that if the diet fell much below the equivalent of 2600 calories per man per day the nutrition of the children did in fact begin to suffer On the other hand, in Glasgow a family diet yielding only 2500 to 2700 calories per man per day is the average in the slum districts, and on this allowance, it is noted, the children grow just as fast as the country children who get more than 3000 calories It is also rather surprising to find that after the ninth month infants which have been fed at the breast show no superiority over those which have been weaned early, but before this time the breast-fed infants are stronger, and there is the possibility of a selective mortality to be borne in mind Careful investigation supported the finding of Prof Karl Pearson that there is little or no connexion between the health of the mother during pregnancy and the nutrition of the child during the first year of its life The physique of the child is affected to a small extent by variations in the general health of the mother, but that is because sickly mothers cannot care for their children properly And here we reach one of the most positive conclusions of the report Maternal efficiency was found to have a more definite effect on the nutrition of the children than any other single factor studied The chief way in which overcrowded homes and small air space hinder the development of children is by influencing the moral and the activities of their mothers On the other hand, it may be feebleness of character that keeps the parents in a bad environment Amongst agricultural labourers and rural miners, whose houses are not so overcrowded, the proportion of inefficient mothers was very small, and it appeared that the few women whose work was unsatisfactory were those whose husbands were badly paid and who had overcrowded homes In Scotland the families of the rural coal-miner are brought up under environmental conditions far better than those of the slums They spend more time in the open air, they are better fed, and nearly all of them are reasonably well looked after in their homes

Poverty brings to bear on the child many forces not easily resolved into their components Of those so far considered—overcrowding, underfeeding, and maternal inefficiency—only the last was shown by the investigators to be definitely correlated with the children's physical condition They expected to find that nutrition would vary as the family income, but no such direct relation was found The contention that a mere increase of wages would, per se, lead to better growth of the children is therefore not supported, and this is one of several conclusions of political as well as medical interest Prof Paton and Prof Findlay set out to gain definite knowledge which would indicate the proper approach to social problems as they affect children Are the large sums spent on child welfare and other schemes directed into the best possible channels? They report

> "The provision of improved housing accommodation by permitting a larger proportion of mothers to care more efficiently for their children and homes might prove to be a beneficial measure What is not demonstrated is that simple increase of income would be followed by improvement in the condition of the children Bad parents, irrespective of their incomes, tend to select bad houses as the money is often spent on other things The saying that 'what is the

ealthy parenchyma to re-expand Selective collapse s not always possible certainly not if a positive ressure is required to effect collapse When starting he second pneumothorax and so throwing out of ction still further lung parenchyma, the greatest rudence is necessary and the process must be xtremely gradual The optimum pressure varies with each individual constant X ray screen xaminations are essential It is obvious that the method of treatment requires more work and care than is necessary for complete collapse This should not be a bar to a more extended trial in this country, especially as it has been shown that the method does not involve undue risk A word of warning should be given Good results although they may occasionally be seen, cannot be reasonably expected when the disease is extensive in one or both lungs. or where adhesions would make satisfactory collapse under positive pressures impossible. In such cases efficient differential partial collapse cannot be obtained

SIXTH BRITISH CONGRESS OF OBSTETRICS AND GYNÆCOLOGY, 1927

The Sixth British Congress of Obstetrics and Gynæcology will be held in Manchester on April 27th, 28th, and 29th, 1927. The principal subject for discussion will be "The Treatment of Inflammatory Conditions of the Uterine Adnexa" and this will occupy the first day of the meeting The remaining days will be devoted to the reading of short papers on obstetrical and gynæcological subjects and demonstrations of surgical operations A museum of pathological specimens of special interest is also being arranged Those intending to take part in the discussion, or to read short papers, are invited to send in their names together with the title of any proposed contribution not later than March 1st, 1927. The secretaries of the Congress are Dr. Daniel Dougal M.C, 11, St John-street, and Dr John Bride, 2, St John-street, Manchester, to whom all communications should be addressed

ALCOHOLIC NERVE BLOCK FOR PAIN IN MALIGNANT DISEASE.

Except in trigeminal neuralgia, the blocking of nerves by alcohol has hitherto found little application More transient blocking by novocaine is useful in many surgical procedures, and its scope has recently been extended by the introduction of paravertebral anæsthesia as a supplementary measure in certain abdominal operations A wider field for the more permanent method is opened up by its adoption for the relief of pain in suitable cases of incurable malignant disease Three examples of its use in this way at the Montefiore Hospital, New York, are described by Swetlow and Weingarten[1] The first was a case of neoplasm of the lung with pain and extreme hyperæsthesia in the left axilla, and later, over the lower part of the left scapula , any movement whatever aggravated the patient's distress and he found it impossible to lie on his left side Physical examination revealed two areas of marked hyperalgesia, one involving the skin segment supplied by the second to the fifth dorsal spinal nerves, the other those supplied by the seventh to the eleventh Three cubic centimetres of a 60 per cent solution of alcohol were injected paravertebrally into the intercostal nerves supplying the hyperalgesic areas and the patient obtained great relief, which continued till his death 33 days later The second case was one of carcinoma of the breast in which involvement of the pleura had given rise to severe stabbing and burning pain An area of hyperalgesia extended from the sixth to the twelfth dorsal segments The corresponding intercostal nerves were injected paravertebrally with 80 per cent alcohol and complete relief was obtained when the patient was seen 58 days later there had been no return of pain The third case was one of carcinoma of the tongue and the nerve injected was the right inferior maxillary Swetlow and Weingarten point out the disadvantages of the constant use of morphia in cases of this kind ; tolerance is quickly acquired and because large doses are necessary to relieve pain the patient often has to be kept in a stupefied state No such objections attend nerve blockage

CORONERS' JURISDICTION TO INVESTIGATE FIRES

Though the Home Office Committee on Coroners reported in 1909 in favour of extending throughout the country the jurisdiction to investigate fires which is at present confined to the City of London, the Government's Coroners (Amendment) Bill now before Parliament does not propose to give effect to this recommendation As a matter of history the coroner's jurisdiction was formerly not restricted to inquiry into cases of death and treasure trove The statute De Officio Coronatoris (4 Edw I , stat 2) contained a list "of what things a coroner shall inquire" The list mentions deaths, woundings. house-breakings treasure trove, rape. wreck and deodands Early legal writers such as the author of the "Mirror of Justices"—an authority said by Maitland to be so full of fables and falsehoods as to be worthless on the subject of criminal law—mentioned also that coroners should inquire into unnatural offences and monstrous births, adding the information that formerly coroners used also to inquire of burnings In later centuries the great commentators of our common law such as Coke Hale, and Comyns, state the coroner's functions in much narrower terms as limited to cases of homicide upon view of the body of the deceased Curious readers will find the subject discussed at length in R v Herford (1860, 29 L J Q.B. 249) A fire occurred in the shop of one Levy Kreigsfeld, a dealer in indiarubber and mackintosh goods in Manchester. The chief constable had his suspicions and suggested to Mr William Herford, the Manchester city coroner that an inquest should be held : but the Court of Queen's Bench intervened and held that the coroner had no fire jurisdiction Chief Justice Cockburn observed that from 1276 (the date of the statute De Officio Coronatoris) down to some 20 years before R v Herford was decided, there seemed to have been a uniform abstinence from the exercise of such a jurisdiction This circumstance, coupled with the fact that the legislature had made no provision for coroners' fees in arson cases led the court to infer that no such jurisdiction existed Thus the matter was settled. and the practice of coroners inquiring into fires was abruptly terminated after showing signs of becoming common As one of the Chief Justice's colleagues pointed out, instances of fire inquiry were found in the City of London In this as in other respects the City has been allowed an exceptional position, and in 1888 the City of London Fire Inquests Act (50 & 51 Vict, c xxxviii.) defined and regulated the fire jurisdiction of the City coroner. The preamble to the Act does not claim any immemorial usage. but merely recites that the origin of many fires taking place within the City of London is undiscovered and that it is desirable that better provision should be made respecting the same Dr F. J Waldo reports that of 186 fire outbreaks which he has personally investigated in the City. 33 were of electrical origin He advocates a Board of Trade inquiry into cases of this sort This suggestion may be the answer to the proposal to extend coroners' jurisdiction to fire investigations throughout the whole country. So long as inquests are restricted to discovering the cause of death the medical profession is immediately interested, and the public interest requires that coroners should possess the qualification of medical knowledge. It is otherwise if the office of coroner is to be universally enlarged to deal with subjects which concern the architect the engineer, and the electrician. Statutory provision has been made for

"Ne quid nimis"

SYMPATHETIC OPHTHALMIA

THE discussion on sympathetic ophthalmia at the recent Oxford Ophthalmological Congress, briefly reported in our columns last week, should prove useful. The opening address was given by Mr. Malcolm Hepburn, who began by referring to the report of a Committee of the Ophthalmological Society in 1886, the gist of which was that when "keratitis punctata" develops in cases of traumatic cyclitis, the only certain measure to prevent complete blindness is excision of the wounded eye. The general trend of Mr. Hepburn's argument was in favour of more conservative treatment. Not every case of cyclitis following injury, he said, even when keratic precipitates are observed, is liable to cause sympathetic disease. How, then, are we to know which eyes can safely be left? Certain facts are undisputed. A penetrating injury which causes cyclitis, whether due to accident or operation, is occasionally followed after a few weeks by a cyclitis of the fellow eye which tends to progress to blindness and in the majority of cases is incurable. This catastrophe is at the present time exceedingly rare, probably owing to the improved standard of asepsis generally adopted in the treatment of wounds; it was almost unknown during the war. Nevertheless, it does occasionally occur, and until recently there has been no certain method of diagnosing which wounded eyes are liable to cause sympathetic disease and which are safe. The consensus of opinion among ophthalmic surgeons has been that those wounded eyes in which keratic precipitates are observed are peculiarly dangerous, and it has generally been considered very risky for a patient with a wounded eye in which the symptoms of an active cyclitis have persisted for as long as three weeks to retain it, even if it still has useful vision. On the other hand, in the case where symptoms of cyclitis have already developed in the fellow eye, since the vision of the exciting eye may ultimately prove to be the better of the two, it is generally thought better to retain it. Obviously, the need is for some means of ascertaining which eyes are actually capable of conveying the infection of sympathetic cyclitis to their fellow. If nothing is done until there are actual signs that the second eye is infected, it may be—and according to some certainly will be—too late. On the other hand, there is now, said Mr. Hepburn, a general consensus of opinion against the possibility of sympathetic inflammation developing many years after an accident, so that we are justified in leaving this part of the subject behind us. If the condition of a wounded eye is obviously hopeless, or if there is no perception of light, it should, of course, be excised. For other cases there were formerly no satisfactory means of certain diagnosis. Recently there has been an improvement in this respect in two directions. It is well known that in certain protozoal diseases—notably syphilis and malaria—there is a definite change in the composition of the blood, the chief feature of which is a marked increase in the number of large mononuclear cells. Some years ago Mr. S. H. Browning, working at Moorfields Hospital, began testing the blood in all cases of eye injury in which the danger of sympathetic disease was considered possible. It was found that in all cases in which the disease was really of a sympathetic nature an exactly similar change in the blood count was observed—i.e., a very marked increase in the number of large mononuclear cells. Acting on this knowledge, it is now customary to treat all cases of eye injury in which this particular condition is found very energetically with full doses of salvarsan or one of the similar arsenical injections. The other recent advance in diagnosis has been made possible by the high magnification under which details can be seen by the aid of the slit-lamp and microscopy of the living eye. Mr. Harrison Butler said that he relied chiefly on this method in difficult cases in deciding whether or not to excise a wounded eye. When sympathetic disease is present, the slit-lamp shows the presence of albuminous matter in the aqueous. It reveals the presence and nature of keratic precipitates deposited on Descemet's membrane and the presence of cells in the fluid of the retro-lental space. He believes that by these signs it is possible to make a definite diagnosis. The existing divergence of opinion about treatment was brought out in the Oxford discussion. No one disputes that excision is not, in many cases, the only possible treatment or that in many others it is the only wise one. The point at issue is whether, once the diagnosis of sympathetic disease has been established, it is ever possible by any means other than excision to prevent the spread of the infection to the second eye. Some, represented at the Congress by Mr. Harrison Butler, maintain that it is not. Others, represented by Mr. Hepburn and Mr. Browning, hold that sometimes it may be. As to the preliminary necessity of accurate diagnosis, there is no divergence of opinion, and Mr. Browning's method of the blood count should always be undertaken in doubtful cases. Where the test proves positive, the ophthalmic surgeon is faced with the responsibility of advising either excision or treatment with arsenical injections. In Mr. Browning's experience many cases have been treated successfully with arsenic even after the appearance of the beginning of cyclitis in the sympathising eye. At any rate, it seems to be established that the success which has already attended this treatment is sufficiently remarkable to necessitate a revision of old ideas.

BILATERAL SELECTIVE ARTIFICIAL PNEUMOTHORAX

THE treatment of pulmonary tuberculosis by "selective collapse" under negative pressure of both lungs was first proposed by Parry Morgan[1] in 1913. He pointed out that the lung was kept at rest only when the pressure was maintained positive, that as soon as the pressure became negative the healthy parenchyma recommenced to expand and function, and that the collapse then became selective (differential). Since then, the trend of opinion has been against high pressures, although complete collapse has been sought and no doubt obtained at refills. No serious attempt appears to have been made in this country to test the value of Parry Morgan's method of treatment. On the other hand, continental and American workers have independently proposed the method, introducing the terms elective and low pressure pneumothorax, and selective collapse. Their work has been followed up so that outside this country there is now a considerable literature on the subject.

In a contribution to the *Presse Medical* of April 24th, 1926, Tobé and Terrasse consider that the possibilities of bilateral pneumothorax should be more realised as it affords a chance of combating with success a complication considered up to the present as beyond the resources of our art. Having discussed the various ways in which infection in the opposite lung develops, they point out that the "alternative" method of doing pneumothorax—viz., letting the lung originally collapsed expand and then collapsing the more recently infected lung—is often not satisfactory, the reason being that the lung originally collapsed is almost always allowed to re-expand too soon. Bilateral pneumothorax has been made possible by the realisation that a small pneumothorax is selective in action, the affected and fibrosed part of the lung collapsing before the healthy areas. Selective action can be obtained on both sides; on the recently affected side by the introduction of small amounts of gas, and on the originally collapsed side by lengthening the intervals between the refills, which allows the

CLXXXIII

ECTOPIC AND UNDESCENDED TESTICLE

THE later stages in the normal descent of the testicle depend upon the development of the gubernaculum which appears about the eighth week of intra-uterine life The gubernaculum when it first appears contains no muscle-fibres; it is a condensation of mesenchyme and consists of densely packed actively growing cells with large oval nuclei which may be regarded as pre-muscle tissue The tissue forming the gubernaculum grows rapidly through the inguinal region of the abdominal wall and soon divides into six separate bundles passing to the scrotum, root of penis, pubis, perineum, inguinal ligament, and saphenous opening These bundles are unequal in size, the largest going to the scrotum It later becomes muscular by the appearance in it of plain muscle-fibres, and by its shortening causes the testicle preceded by the processus vaginalis to descend from the posterior abdominal wall through the inguinal canal into the scrotum

Forms of Ectopia

In cases of undescended testicle the gubernaculum has not acted efficiently and the testicle remains in the inguinal canal, at the external abdominal ring, or in the upper part of the scrotum In cases of ectopia, the gubernaculum, for some reason unknown, is believed to become separated from the body of the testicle The testicle, now without a guide, is left to pick out its own path, and naturally chooses the path of least resistance As it travels inwards from the external abdominal ring, it finds itself in an extensive fascial space between the deep lamina of the superficial fascia of the abdominal wall and the aponeurosis of the external oblique Having entered this space, the only control to which the testicle is subjected is in the extent of its migration, and this depends solely upon the length of the spermatic cord A short cord may hold up the testicle immediately the latter enters the space, and the testicle comes finally to rest just internal to, and as a rule slightly above, the external abdominal ring Given a long cord which will not hamper onward progress the testicle may have many possible destinations Its general trend, however, will be downwards

Finally it will occupy either of two positions—the dorsum of the penis or the perineum In *penile ectopia*, the testicle passes inwards towards the symphysis and comes into relation with the penile root Passing downwards from this situation, it finally comes to rest beneath the subcutaneous tissues on the dorsum of the penis

In *perineal ectopia*, the testicle passes downwards over the pubic crest and passes into the perineal division of the fascial space Here its further progress becomes barred by the attachments of Colles's fascia and the transversus perinei superficialis It finally comes to rest about one inch in front of the anal margin, to one or other side of the mid-line

The other forms of ectopia are extremely rare Perhaps the most common of them is the *crural* type, in which the testicle is found lying in Scarpa's triangle, in the neighbourhood of the saphenous opening The condition is associated with an abnormally long mesorchium As the testicle approaches the internal abdominal ring, the long mesorchium fails to exercise its customary control, and instead of the testicle being brought close up to the internal ring it sags downwards to the crural ring

Operative Measures

Expectant treatment should only be adopted in young children, as it is only in very few cases after the age of 4 years that the testicle will descend on its own account Operative treatment is always indicated since complications frequently accompany, or arise in association with, imperfect migration of the testicle The commonest of these are hernia hydrocele, inflammation of the testicle, torsion of the spermatic cord, and malignant disease

This may be considered under three headings. (1) Orchidopexy, or fixation of the testicle in the scrotum (2) Orchido-cœlioplasty, or replacement in the abdominal cavity. (3) Orchidectomy or removal

The first is obviously the most logical procedure for it aims at replacing the testicle in its normal position Unfortunately, it frequently fails because in many cases the testicle cannot be brought down into the scrotum without division of the spermatic artery Should this division be made the testicle is dependent upon the artery of the vas alone for its blood-supply—a blood-supply which is quite inefficient for the proper growth and development of the testicle In any operation the integrity of the essential structures of the cord must be maintained

Not only should the vas deferens and its blood-vessels be mobilised most carefully along the course of the entire inguinal canal but the intrapelvic portion of the vas deferens and its companion vessels should also be freed The firm connective-tissue bands, which often fix the spermatic cord to the pelvic tissue, should be divided with scissors Although owing to their relative shortness the blood-vessels may interfere with the lowering of the testis to a greater extent than does the vas, they must never be divided if orchidopexy is to be successful In ectopia testis the same principles apply, and in most cases of ectopia it is possible to bring the testicle down into the scrotum and obtain permanent anchorage

Orchidopexy

The following technique is recommended —

An oblique incision is made over the inguinal canal and the aponeurosis of the external oblique muscle exposed, this in turn is split from the external abdominal ring to well beyond the position of the internal abdominal ring That part of the gubernaculum which is continuous with the lower border of the processus vaginalis is freed from its attachment to the scrotum and a Spencer-Wells forceps is applied to it in order to facilitate traction on the cord without causing any injury to the testicle A pouch is prepared for the testicle by pushing the forefinger into the scrotum The fibres of the cremaster muscle are divided and the sac opened high up near the internal abdominal ring, the testicle is exposed seemingly within the congenital peritoneal sac Great care should be exercised in separating the sac from the spermatic cord, as the vessels are spread out on its posterior surface as a broad band, and any traumatism to the spermatic vessels in childhood is almost invariably followed by atrophy The peritoneal sac is dissected up to the internal abdominal ring and transfixed A tunica vaginalis is formed from the fundus of the sac by a purse-string suture Care should be taken not to handle the denuded testicle otherwise post-operative swelling may occur. A finger is now passed behind the upper part of the inguinal canal and the internal ring dilated The vas can be seen leaving the spermatic vessels at the internal ring and thence passes downwards and inwards As a rule there is little difficulty in obtaining sufficient length to the vas, but to ensure its proper relaxation the fascia of the transversalis abdominis muscle can be split downwards from the internal abdominal ring to the deep epigastric artery

Division of the deep epigastric vessels or the transposition of the testicle and spermatic cord behind them, as advocated by some surgeons, yields an insignificant increase in the length of the cord, the only structure to benefit by this procedure is the vas with which there is rarely any difficulty The peritoneum is lifted up from the posterior abdominal wall by a small retractor and any fibrous bands or adhesions connecting the spermatic vessels to the posterior abdominal wall are divided with scissors By this means the spermatic cord is sufficiently lengthened to allow the testicle to lie without any tension in the bottom of the scrotum A needle threaded with silk is passed through the lower part of the gubernaculum which is attached to the testicle and through the scrotum, both ends of this suture are fixed to a Cheyne's testicle frame when the inguinal wound has been closed The entrance to the scrotum below the pubic spine is closed over the cord with a purse-string suture The conjoined tendon is then sutured to Poupart's ligament above the vas and the other layers of the abdominal wall are closed as in a radical cure for hernia the departmental investigation of accidents in factories and mines, at sea, or on railways The Air Ministry can inquire into the cause of aerial disasters, the Home Office into that of explosions and the Ministry of Transport into traffic accidents within the London traffic area Similar departmental power to investigate the cause of serious fires might well be provided

SYNCOPE IN PAROXYSMAL TACHYCARDIA

IN the December number of the *Bulletins et Memoires de la Societe Medicale des Hôpitaux de Bucarest* Dr. Iliescu records a case of paroxysmal tachycardia of ventricular origin in which Stokes-Adams attacks accompanied the longer paroxysms The patient was a woman, aged 60, who had been subject to syncopal attacks for the past 12 months At the beginning of her illness the paroxysms were associated only with palpitation, but later they were accompanied by dizziness, and finally by loss of consciousness and convulsions Between the attacks the electrocardiogram showed complete heart-block, the ventricular rate being in the neighbourhood of 32 per minute, while during the attacks it rose to over 200 At the beginning of an attack the ventricular rate rose slowly from 30 to 50 per minute, this was followed by a short period in which isolated ventricular extrasystoles appeared in the record and then paroxysmal ventricular tachycardia supervened When the attack lasted only a few seconds the radial pulse remained perceptible, but during the more prolonged attacks the pulse entirely disappeared, no heart sounds were audible, and the electrocardiogram exhibited a degree of regularity which led Dr Iliescu to describe the condition as "ventricular flutter" The fact that the attacks when untreated tended to occur in groups of ten or more made it possible to study the response of the heart to various drugs On two occasions during a period of slow heart action a single dose of quinidine (0 4 g) induced an attack which was preceded by a short period of bigeminal heart action Pilocarpine and adrenalin were given during the attacks on more than one occasion without effect Atropine stopped the attacks and its daily administration greatly reduced their frequency and rendered them much less severe It is interesting to note that the effect of both quinidine and atropine in this patient was the opposite of that obtained in a case of ventricular tachycardia reported by R W Scott, in which the attacks were induced by atropine and controlled by quinidine The association of syncopal attacks with tachycardia is a rare condition, but cases have been reported by C Esmein and E Donzelot, and by E Savini in France, by A D Hirschfelder and by A R Barnes in America, as well as by G A Allan in this country Allan's case, which was reported in a recent number of the *Glasgow Medical Journal*, occurred in a man, aged 53, who had been subject to syncopal attacks for 12 years but in whom there was no evidence of any organic cardiac lesion The attacks were of short duration, the longest while under observation lasting only 23 seconds, but at times they occurred with great frequency During the attacks the heart-rate was from 230 to 270 per minute In Allan's case, as in one reported by Strong and Levine, the spacing of the ventricular complexes was much less regular than that which is found in paroxysms of supraventricular origin, and as in Scott's case quinidine produced a beneficial effect on the condition

Dr Wu Lien Teh (G L Tuck), Director and Chief Medical Officer of the Manchurian Plague Prevention Service and physician extraordinary to several successive presidents of China, is the first non-Japanese to receive from the Imperial University of Tokio, Japan its most distinguished diploma, the *igaku-hakushi* This has been awarded him for a thesis on Pneumonic Plague Dr Tuck, as he was familiarly known in England, graduated M A , M B Camb in 1902 and M D. in 1905

Sir John Gilmour has been sworn as Secretary of State for Scotland—the office has not hitherto ranked as a Secretaryship of State—and Major Walter Elliot, M P , has been appointed Parliamentary Under Secretary of State

INDEX TO "THE LANCET," VOL I, 1926

THE Index and Title-page to Vol I, 1926, which was completed with the issue of June 26th, will shortly be published A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

L Freeman is granted a short service commission as a Flying Officer for 3 years on the active list

The undermentioned officers of the Army Dental Corps are granted temporary commissions in the ranks stated on attachment to the R A F J G Worsley (Major), Squadron Leader, T K Place (Capt), H J Proctor (Capt), and H O Sumerling (Capt), Flight Lts

The undermentioned officers of the Army Dental Corps relinquish their temporary R A F commissions on return to Army duty Squadron Leader D Blair (Major), Flight Lts R M King (Capt), D H W Williamson (Capt), and A Williams (Capt)

Flight Lt W G Weston relinquishes his temporary commission on ceasing to be employed

ROYAL ARMY MEDICAL CORPS OBLIGATIONS OF OFFICERS

An officer of the R A M C who undergoes in future the Senior Course of Instruction for Captains prior to promotion to major, or a Specialist Course, will be required to sign an honourable undertaking to continue to serve in the Army after the termination of the course for a minimum period of three years This will not preclude the Army Council from releasing him from his obligation should the circumstances justify release, but an officer who receives permission to resign his commission before the expiration of the period for which he undertakes to serve, will be required to join the Regular Army Reserve of Officers

Sir Edward Marshall-Hall was urging the arguments six years ago in R. v. Holt (15 Cr. A.R., p. 10); he contended then that it was the duty of the lawyer to keep pace with the scientist. Indeed, the legal view was nearer to the medical view then than now, for in Holt's case, as Lord Reading, C.J., has pointed out, the trial judge did at least leave the question of uncontrollable impulse to the jury, though the jury's verdict negatived the defence founded thereon. The later cases seem to show a stiffening of the legal view. In 1921, for example, in R. v. Quarmby (15 Cr. A.R., p. 163) counsel for the defence argued that the subconscious mind of a person afflicted with delusions was a factor to be considered in connexion with acts committed by one whose unrestrained passions resulted in crime. "The King's Bench determines the existing law," said Darling, J., on that occasion, "not what the law might be if amended by the legislature." "Foreign and colonial codes," added Sankey, J., "admit the defence of irresistible impulse; English law does not." In the following year Sir H. Curtis Bennett plied Mr. Justice McCardie with arguments on "impulsive insanity" in the case of Ronald True and addressed the Court of Criminal Appeal to the same effect, but without securing an acquittal. The latter court showed itself even more hostile to the theory of uncontrollable impulse in R. v. Kopsch last year (19 Cr. A.R., p. 50). Kopsch strangled a Mrs. Thornton in Ken Wood with his necktie; they had been lovers, and his defence was that she asked him to strangle her and that he acted under an impulse which he could not control. Lord Hewart, C.J., was severe upon the defence. "The court," he said, "has to-day had a repetition of an argument which from time to time is heard here, with an ingredient added that is not common—namely that, according to the experience of counsel for the defence, His Majesty's judges are continually summing up to juries on the question of insanity in the way for which he has contended. That statement is surprising. No such summing up is known to this court. The law with regard to criminal insanity is that every man is presumed to be sane and to possess a sufficient degree of reason to be responsible for his crimes until the contrary is proved to the satisfaction of the jury. To establish a defence on the ground of insanity, it must be clearly proved that, at the time of the committing of the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or if he did know it, that he did not know he was doing what was wrong." Having thus laid down the existing law, the Lord Chief Justice criticised the arguments for the defence as having drifted round to the contention that the law ought to become what he stigmatised as the "fantastic theory of uncontrollable impulse which, if it were to become part of our criminal law, would be merely subversive." It is not yet part of the criminal law, added Lord Hewart, and he hoped the day was far distant when it would be made so.

With profound respect to the learned Lord Chief Justice, one may ask whether he has not overstated the position. Can a doctrine be unknown when Mr. Justice Greer expounded it to the jury in Holt's case? Can it be fantastic and subversive when so staid and cautious a body as the Atkin Committee gave it support? Lord Justice Atkin's *colleagues* included official lawyers like the present Master of the Rolls (then Attorney-General) and Sir Leslie Scott (then Solicitor-General), authorities deeply versed in criminal prosecutions like Sir Herbert Stephen, Sir Richard Muir, and Sir Archibald Bodkin, and Home Office representatives like Sir Edward Troup and Sir Ernley Blackwell. These gentlemen stated in their report that they were satisfied that cases of mental disorder did exist where the impulse to do a criminal act recurs with increasing force until it is, in fact, uncontrollable. They found that cases were not uncommon in which mothers normally devoted to their children cut their children's throats or otherwise took their lives. In such cases, they said, the accused knows the nature of his act and knows that it is wrong, and the McNaghten formula is not logically sufficient. "We think," said the Committee, "that it would be right that such cases should be brought expressly within the law by decision or statute. We think that it should be made clear that the law does recognise irresponsibility on the ground of insanity where the act was committed under an impulse which the prisoner was, by mental disease, in substance deprived of any power to resist." The Committee gave some grounds for thinking that the existing law was already as thus stated. "No doubt some judges have charged juries to that effect; on the other hand, there seem to be definite decisions of the Court of Criminal Appeal the other way. It seems to us that, if this legal doubt should continue, it would be advisable to make the law clear by an express statutory provision. We have no doubt that, if this matter were settled, most of the criticisms from the medical point of view would disappear."

The Atkin Committee was remarkably conservative and cautious. It made this modest contribution to settle the controversy between law and medicine, but the recommendation put forward with such high authority has been ignored. The suggested rule has been confirmed neither by statute nor by decision. The Court of Criminal Appeal faces the arguments of the Committee with a blank negative. Have the Lord Chancellor and the Home Office thrown the Atkin Committee over?

The Mystery of the Fishmongers.

Two fish salesmen were fined £50 each with £5 5*s.* costs at the Mansion House some days ago for selling putrid fish at Billingsgate. One had sold two boxes containing 24 hake, the other had sold 57 lobsters unfit for human consumption. The defendants attributed the sale to the slackness of their servants, who let the fish pass without sufficient examination. More recently three other fish salesmen of Billingsgate Market were each fined £25 with £3 3*s.* costs for selling a box containing 27 codfish which were unfit for human food, the charge being made under Section 47 (2) of the Public Health (London) Act of 1891. On both occasions the prosecutions were undertaken by the Fishmongers' Company under a charter of 1604. At that date King James I. reincorporated the "wardens and commonalty of the Mystery of Fishmongers in the City of London" and gave them the usual powers to make laws for the good government of the mystery. The company received rights of survey, search, government, and correction of all persons whatsoever selling, having, or possessing any fish. Power was given to enter premises and to view, search, and survey whether the fish be wholesome for man's body and fit to be sold or no, and, if found unwholesome, corrupt, or unfit to be sold, to seize and dispose of it. It was under these powers that the Fishmongers' Company acted in the recent prosecution. The status and capacities of this ancient corporation were expressly recognised in the Salmon and Freshwater Fisheries Act of 1924 (Sections 34 (2), (4), and 78 (*d*)). It is in keeping with immemorial traditions of municipal life in this country that each trade should be organised to supervise its own members. The Mystery of the Fishmongers has always attached great importance to its duties of supervising fish supplies. Our city companies amply justify their existence by undertaking such work in the interests of the community.

Prison Clothing.

An unusual action was lately heard in the Bedford county court when a man who had been placed in Bedford prison on remand claimed £100 damages against the late governor of the prison for removal of his clothing. The judge awarded £5 5*s.* damages with costs and spoke strongly of the repulsive result of compelling a man of decent upbringing to wear underclothes previously worn by persons who were often verminous and sometimes diseased. It was not apparently suggested that the plaintiff in this case

The patient is kept in bed for a fortnight, and a careful watch is kept upon the ligature to see that it is always tight It is a good plan to increase the tension slightly every second day by untying the knot and refastening it Sometimes the constant traction on the ligature causes it to cut its way out about the tenth day if this does not occur it may be pulled through by traction upon one end

Orchido-cœlioplasty

The operation for the replacement of the testicle in the abdomen is very similar to that of orchidopexy except that instead of bringing the testicle down into the scrotum it is placed in a bed made for it in the extraperitoneal tissue and retained there by catgut sutures The hernial sac is dealt with as in a radical cure for hernia

Orchidectomy.

When the testicle is to be removed the inguinal canal is exposed by an oblique incision similar to that used in orchidopexy The testicle within the processus vaginalis is freed up to the internal abdominal ring The spermatic cord is ligatured at the abdominal ring and the testicle removed Two or three catgut sutures are passed from the deep aspect of Poupart's ligament to the conjoined tendon and tied, thus obliterating the inguinal canal The external oblique is then united by a continuous catgut suture, and the skin closed by a continuous silkworm gut suture

The End-results of Treatment

As regards function, patients with bilateral undescended testicles are found to be sterile On microscopical examination of over 50 undescended testicles removed by different surgeons I have not been able to find any normal genital cells or spermatozoa in any of the specimens examined The operation itself often fails in anchoring the testicle in the scrotum, for in cases examined several years after operation the testicle is often found high up in the scrotum or at the external abdominal ring

It may be said Why should an operation be performed at all? First, complications may arise in connexion with an undescended testicle; these have already been mentioned Secondly, there are definite and important social reasons for operation The position could not be put better than in the words of a recent leading article in The Lancet (1926, i, 353) "The genital organs carry such an emotional charge that, even though they remain concealed in ordinary circumstances, the reactions of the individual to any loss or defect are often greater than when he bears a loss literally upon his face. Moreover, in the case of children, we must bear in mind that mental development in the psycho-sexual sphere is so powerful in determining the whole behaviour of the individual that, apart from endocrine influence, the physical state of the genitalia as they appear to the person concerned must play a part, though its extent may be debatable, in fashioning his reaction modes and character traits"

Conclusion

In conclusion, it may be said that in those cases where there is an imperfectly descended testicle on one side and a well-developed fully descended testicle on the other, the partly descended testicle should be removed, unless it can be brought down into the scrotum without any tension or division of any of the constituents of the spermatic cord In bilateral cases it is advisable to take means to preserve the internal secretion on both sides and not to sacrifice the gland An attempt should be made to bring one testicle into the scrotum, in order that some chance of fertility may be afforded the patient, and to return the other testicle to the abdomen

MEDICINE AND THE LAW

Mr Harnett's Appeal

The judgment of Mr Justice Horridge dismissing Mr. Harnett's action against Dr Holdrich Fisher (for damages for negligence in certifying him to be a lunatic in 1912) has been upheld by the Court of Appeal The point was a short one Mr Harnett escaped from the asylum at Croydon in 1921, and commenced his action by writ at the end of May, 1922 Two sections of the Statute of Limitations were material Section 3 enacts that actions such as Mr Harnett's must be begun within six years after the cause of action arises, Section 7 enacts that this time-limit shall not apply if the plaintiff is *non compos mentis* It was of the essence of Mr Harnett's action that he was not insane in 1912 when his cause of action arose; a jury found in his favour on this point But if he was sane in 1912, he could not simultaneously be *non compos mentis* so as to evade the Statute of Limitations The Master of the Rolls observed that he felt compelled to say that great hardship might be occasioned to a defendant if a cause of action should survive so long as Mr. Harnett's against Dr. Fisher It was, indeed, to avoid that hardship that the Statute was passed The appeal, however, though dismissed, was dismissed without costs, inasmuch as the appellant had obtained the verdict of the jury on the issue of his sanity and had been awarded £500 damages Mr Harnett, of course, lost the benefit of that verdict and those damages when Mr Justice Horridge dismissed his claim, but they remained an element in the case which won him the sympathy of the Court of Appeal on the question of costs

Irresistible Impulse

The Court of Criminal Appeal on July 12th refused to accept the principle that irresistible impulse may be a good defence in criminal trials The appeal was that of Joseph Edward Flavell, convicted at Worcester Assizes of the murder of his step-brother Flavell was 24 years of age, but was described as having the intelligence of a boy of 14 or 15 His father died at 31 from Bright's disease and epilepsy; no fewer than eight of the appellant's blood relations had either died in, or been confined in, lunatic asylums Flavell had got up in the night, put on his best clothes, gone downstairs, procured a wood-chopper and killed his step-brother as he lay in bed with two blows severe enough to cause instantaneous death He was convicted of murder, and his appeal failed, though the Home Office has since commuted his sentence Sir Edward Marshall-Hall, for the defence, recalled the recommendation made in 1923 by Lord Justice Atkin's Committee[1] to the following effect "It should be recognised that a person charged criminally with an offence is irresponsible for his act when the act is committed under an impulse which the prisoner was by mental disease in substance deprived of any power to resist" The Committee added that it might require legislation to bring this rule into effect, but, as Sir Edward Marshall-Hall observed, Parliament has done nothing, and now the judges have once more refused to intervene The Court of Criminal Appeal gave its usual answer that the judge had summed up fairly at the trial, and the jury had found a verdict supported by evidence, and that the further disposal of the accused man rested with the Home Office In fact, we are back where we were before the case of Ronald True focused public attention upon the discrepancies between legal and medical theories of criminal responsibility, and before the Lord Chancellor set up the Atkin Committee

---

[1] The Lancet, Dec 8th, 1923, p 1262

The Government has given nearly a lakh of rupees as a non-recurring grant to meet the cost of equipment, and has increased its annual grant from Rs 200,000 to Rs 311,000, so that the financial difficulties which have hindered the work of the college during the last four years are now at an end The hospital attached has 200 beds and the educational facilities are adequate

From the Madras Presidency it is reported that the medical schools have in recent years shown a decline both in strength and admissions, in spite of the fact that an additional school—the Lady Willingdon Medical School for Women—has been established The decrease in applications for admission is partly attributed to the abolition of the stipendiary system and the small chances of Government employment now open to candidates passing out of the schools

The general fear of unsatisfactory employment was shown at a conference of the All-India Medical Licentiates' Association held at Lahore last May, when there was evidence of a demand on the part of the licentiates that their present curriculum of four years should be extended to five years in the hope that the extension would assimilate their status to that of university graduates This solution, however, might not have the desired effect Colonel Chambers, Professor of Medicine at the Lahore Medical College, who presided over the conference, said that the extension of the medical school course by one year would make the licentiate's training more costly without necessarily improving his prospects, and that if the demand were granted it might lead to the abolition of the licentiates Already the supply of graduates was greatly in excess of the existing demand, with the result that graduates were prepared to work in place of sub-assistant surgeons in rural dispensaries

Five hundred students at the National Medical College at Calcutta recently went on strike in order to compel the authorities to apply for affiliation to the Medical Board As things stand at present, students who have passed out of the Calcutta National Medical College are liable to prosecution under the Bogus Degrees Medical Act, since the institution is not recognised by Government

Midwives Registration Act

The Madras Legislative Council has passed a draft Bill for the registration of nurses and midwives in the Presidency It is proposed to register all qualified and trained nurses and midwives, and in addition the Government has accepted the scheme for the training of *dhais*, or barber-midwives, and for their registration The *dhais* will be given systematic training at district headquarter, municipal, and taluk headquarter hospitals approved by the surgeon-general, they will receive a stipend of Rs 7 8 a month while being trained, and after not less than six months' training they will be examined by the district medical officers and matrons at the district headquarters Those who are certified will be entitled to practise in rural areas, but they will not be eligible for employment in Government, local fund, or municipal service, and they will be re-examined by district medical officers once every two years in order to ensure that they are still efficient These barber-midwives will be encouraged to call in outside aid or to take the cases to the hospitals whenever necessary, and for every such case they are to be granted a reward of one rupee by the local body concerned

Internal Opium Policy

The Government of India has published a resolution stating that its policy based on the finding of the Royal Commission of 1893, has been and is one of non-interference with the moderate use of raw opium On the other hand, over-indulgence must, as far as possible, be suppressed, and though much has been done to reduce the consumption of opium as a whole, there are still black spots on the map of India which the Government is anxious to remove In regard to the administration of opium to children, the Government accepts the view that education and child welfare propaganda are the only expedients likely to give satisfactory results In conclusion, the resolution states that prohibition of the use of opium for non-medical purposes would be impracticable, but efforts are to be made to check smuggling, and special attention will be devoted to areas where consumption is unduly high

St John Ambulance Association

Presenting the annual report of the St John Ambulance Association on June 24th at Simla, Sir William Birdwood said that railways, police, educational institutions, gaols, mines, and Indian States were taking their share in the movement, amongst the 10,340 persons who had passed the course during the year were 1880 railway employees A notable feature of the year was the advance of the work in gaols For the first time in the history of the Association a large number of teams, consisting of convicts and warders and boys from the reformatory schools, had taken part in the All-India Ambulance Competition

Medical inspectors of schools are being appointed to the important towns in the United Provinces

The total number of patients treated at the Punjab Mental Hospital, Lahore, during 1925 was 1154 and the average daily strength was 864 The death-rate was 14 2 per cent of the daily average population, more than half the deaths being due to dysentery and diarrhœa

The Bengal Government has decided to devote 2 lakhs of rupees (£14,000) to an intensive campaign against kala-azar Several hundred treatment centres will be opened throughout the province under the control of the district boards

Lieut -Colonel K V Kukday, inspector-general of civil hospitals, Central Provinces, opened a new hostel at Nagpur on July 1st

The ninth annual report of the King Edward VII Pasteur Institute and Medical Research Institute of Shillong states that there were only 8 deaths from hydrophobia in 980 cases of dog bite, and 3 deaths in 165 cases of jackal bite

BERLIN.

(FROM OUR OWN CORRESPONDENT)

Overcrowding of the Medical Profession

OVERCROWDING of the profession has led the Hartmann-Bund, the great medical union, to take energetic steps According to the law a medical man may settle where he likes, but as a matter of fact, with a few exceptions, he cannot earn a living without being admitted to club practice The indiscriminate admission to club practice, known as the free choice system, and described in my letters on several occasions, has given satisfaction to the club members but not to the profession in general Owing to the great number of club doctors, the share of the club fees which individual medical men receive grows smaller and smaller The few existing restrictions—notably that in certain great towns a medical man before being admitted to club practice must have resided in the town for at least three years—have little effect in diminishing the number of club doctors The general assembly of the Hartmann-Bund, which has lately been held in Eisenach, has now decided that medical men over 70 years of age who voluntarily retire from club practice shall be entitled to an annuity from the Bund of at least 1200 to 3000 marks (£60–£150) In certain circumstances, also, medical men over 60 are to have the same privilege, provided that necessary means are at the disposal of the Bund The funds will be collected from different sources, and the first step will be to raise the subscription by 1 mark a month As the Bund has 39,000 members this should mean an increased income of 770 000 marks (£23,500) a year The local branches will be authorised to raise special contributions, and the admission fee will be increased had been compelled to put on verminous or infected clothing, otherwise the damages would doubtless have been heavier The Prisons Rules for England, like the corresponding code more recently issued for Scotland, naturally direct that every convicted prisoner must be provided with a prison dress and shall be required to wear it But a person remanded to a prison is very far from being a convicted prisoner According to the English rules a prisoner awaiting trial may wear prison dress if he desires it; apparently he cannot be compelled to do so unless his own clothes are insufficient or unfit for use or are necessary to be preserved for the purposes of justice, or except during a period when his own clothes are being disinfected to prevent the introduction or spread of infectious disease The county court judge said he was satisfied that the late governor of the prison, who was being sued, was responsible for what had occurred; he added that his judgment would emphasise his strong opinion that there was persistent infraction of one of the most important rules in favour of a prisoner The incident gives rise to wonder whether the prison visitors pay attention to this point, and whether the Prisons Rules are sufficiently explicit or whether the fault lies in their non-observance

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

PRESENTATION TO DR ANDREW BALFOUR

THE members of the teaching staff of the London School of Hygiene and Tropical Medicine assembled in the library on Friday last, July 23rd, in order to present the Director, Dr Andrew Balfour, with a picture by Mr A O Lamplough as a token of esteem, and in recognition of his great services to the School The presentation was made by Prof R T Hewlett, who said —

Dr Andrew Balfour,—We are gathered here to-day to make you a little presentation as a token of goodwill and esteem in which you are held not only by your colleagues of this School, but by many other outside friends If you will look at the list of those who have contributed to this presentation you will find that it includes a representative of the Rockefeller Foundation, past and present members of the teaching staff of the School, members of the staff of the Tropical Diseases Hospital, representatives of the Seamen's Hospital Society, members of the Bureau of Hygiene and Tropical Diseases, and of your administrative staff (and in this connexion Mr Harris writes to say how sorry he is to be unable to be present to-day and how proud he is to serve under you) Many years ago—more years probably than either you or I care to reckon—I had the honour and pleasure of being present at a dinner to bid you farewell on your approaching departure for Khartoum

I little thought then—a score of years or more ago—that I should in the future be the unworthy mouthpiece of those who desire in a sense to welcome you back again in the important and honourable post of Director of the London School of Hygiene and Tropical Medicine I need hardly say how glad I am to do this and appreciate the call, though I am bound to say I suspect it is a somewhat dubious compliment to myself based on length of service and grey hairs rather than on actual merit!

We have now reached what may, perhaps, be regarded as the third stage in the career of the School of Hygiene The first stage was the noble gift by the Rockefeller trustees of funds for the foundation of the School The second stage was the altogether admirable appointment of yourself as Director of the School, and the third stage was initiated the other day by the laying of the foundation-stone of the permanent home of the School

Some of us of the old London School of Tropical Medicine, so successful in the past under the ægis of the Seamen's Hospital Society, to whom a warm tribute ought to be paid for their wisdom and foresight in undertaking so desirable, though at the same time so great, a venture, some of us of the old Tropical School may feel some regret at its disappearance as a separate entity, for believe me under the inspiration and leadership of Sir Patrick Manson we throve wonderfully and were a very happy family. But all of us, I think agree that the incorporation of the Tropical School in the new School of Hygiene was a right and proper step, and we in particular, members of the old Tropical School, welcome your appointment as Director because we believe that the great Mansonian tradition will be worthily maintained in your hands as regards the tropical side of the School's activities

As regards other activities of the School, in your hands, too we may rest assured that they will be in equally safe keeping The physical side of health training certainly will, for have you not won, if not spurs, at least many hacks and bruises on university and international football fields? You have experience of public health administration, you have travelled widely and have a broad outlook on health problems, you are a research worker and know the importance of a live school combining teaching with research When I look at the list of decorations and degrees you have acquired, of the prizes you have won, of the appointments you have held, of the campaigns in which you have taken part, and of the committees upon which you have served, I begin to ask myself Has Scotland produced only *one* Admirable Crichton?

Moreover, by your silver speech and ready pen you do much for the School Was not the last named (your ready pen) partially trained in the realm of romantic fiction We may be sure you will not be "Cashiered," may we hope that your course may be a smooth one, not determined "By Stroke of Sword" nor recourse "To Arms," and that in your present post you have in some degree entered into 'The Golden Kingdom "

This little gift which we have for you I beg you to accept firstly, as a welcome (somewhat belated perhaps) to the School, secondly, as an appreciation of all you have done for the organisation of the School activities and of the inauguration of its permanent home, and thirdly, as a token of cordial esteem and goodwill from colleagues and other friends. It may also serve to remind you of the time you have spent in tropical climes in the service of humanity and of your country

Finally, it is a pleasant supplement to the presentation to yourself to ask Mrs Balfour, your closest colleague, kindly to accept this rose-bowl as a memento of this occasion.

Dr Andrew Balfour, in reply, expressed his thanks at the welcome given him by the staff of the School in the arduous task of reorganisation of its activities, and expressed his hopes for the future prosperity and success of the School of Hygiene and Tropical Medicine based upon the loyalty of the present staff

The presentation picture was one of the artist's well-known Eastern effects, representing a Sudanese on his camel, and recalling Dr Balfour's distinguished services in the Sudan and his activities as advisor to the Forces in Central Africa during the war

NOTES FROM INDIA

(By our own Correspondents)

The Supply of Quinine

THE Madras Government Cinchona Department has begun new plantations in the Anamalais Hills where the Government possesses fully 20,000 acres suitable for growing cinchona More than 50 acres were planted before the present monsoon, and it is hoped that in a very short time the bark available from these and other sources will make India independent of foreign supplies During the year 1924-25, 280,000 lb of bark were harvested from Government plantations, and the Madras factory produced over 23,000 lb of quinine sulphate, besides 362 lb of quinine bihydrochloride and a smaller amount of bisulphate The output of cinchona febrifuge was 1143 lb and its popularity is evidently increasing An official test made in the Madras hospitals two years ago showed that the febrifuge has great potentialities in the treatment of benign tertian infections, though it still remains to be seen whether it is effective in preventing the relapses which are the real problem in malaria Further work on the periodides of quinine and quinidine indicate that experiments with these salts would be well worth while, and supplies are offered for research purposes

Medical Education

In different parts of India there are now 256 women studying for medical degrees of whom 198 are Indians At the Lady Hardinge Medical College at Delhi the number of students is at present 106, they are drawn from 14 different Provinces and States, and represent many different nationalities and religious beliefs examined by two doctors, and were again examined on landing The picture on the return journey was remarkably different No examination of passengers was made before embarking, no routine examination on board, and none on landing He suggested that passengers on liners bound for Ireland should be examined en route by the doctor on board, and infectious cases reported by him to the port authorities at the port of disembarkation Dr T P O'Reilly (Cavan) pointed out that in Ireland during the decade 1901–1910 the average annual mortality from all forms of tuberculosis was 2 63 per 1000 of the population In 1923 the rate had fallen in the Saorstat to almost half—to 1 41 per 1000 In 1924 the rate rose to 1 45, and in 1925 to 1 48 Dr B O'Beirne (Galway) believed that the isolation of advanced cases was far more important than the treatment of the individual, comparatively, and that too much attention was being paid to the diagnosis of "early" cases, and, comparatively, too little to stopping the spread of infection Dr T Reynolds (Leitrim) gave an outline of a scheme of orthopædics of English origin, and suggested the institution of a central orthopædic hospital near Dublin, staffed by whole-time orthopædic surgeons

Committee on Milk Supply

The first meeting of this Committee was held on July 14th in the offices of the Department of Local Government and Public Health The members are Mr R Wilson, T D (Chairman), Dr T Hennessey, T D Mr P K Hogan T D, Dr E F Stephenson, Dr M J Russell, Mr P F Dolan, M R C V S, Mr J Johnston, Mr P O'Connor, Mr L S Smith, and Mr E P McCarron, Secretary to the Department of Local Government and Public Health It was decided that copies of the regulations and other available literature dealing with the cleanliness and wholesomeness of the milk supply should be furnished to each member of the Committee, that evidence should at the outset be invited from the Dublin Corporation, organisations connected with the Dublin milk supply, Irish Agricultural Organisation Society, Irish Farmers' Union, Creamery Managers' Association, and inspectors of the Local Government Department, and that a summary of transactions at each meeting should be circulated for publication It was arranged to hold the next meeting after the recess on a date to be fixed by the chairman The Committee will be prepared to hear any person who notifies his readiness to give evidence and submits a précis to the Secretary, Committee on Milk Supply Department of Local Government and Public Health, Upper Merrion-street, Dublin

University of Dublin Trinity College

A three weeks' post-graduate course has been arranged for Sept 13th to Oct 2nd The course will be conducted as in former years and will consist of clinical meetings at hospitals in the morning and laboratory classes in the medical school in the afternoon Arrangements have been made for a limited number of members of the class to reside in College rooms A prospectus, giving details of the course and cost, may be obtained on application to the Honorary Secretary, School of Physic, Trinity College, Dublin

---

HOSPITALS AND MOTOR ACCIDENTS —At an inquest last week the house surgeon of Bedford Hospital stated that one bed in three in that institution was occupied by the victim of a motor accident

THE LONDON HOSPITAL —The annual report records that the death rate in 1925 was the lowest on record—4 58 per cent The decline of the rate in recent years is attributed to increased skill in the diagnosis of disease in its early stages and to the admission of a larger proportion of cases for preventive treatment The total number of beds in use was 810 but 101 were still closed The cost of each patient was £11 7*s* 7*d* and the average length of stay 14 days The income for general purposes was £240,000 and the expenditure £260 000

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

THE following are statistics for 1925 from districts whose health reports are reviewed below .—

Name of district	Estimated mid year population (R G)	Birth rate	Death-rates per 1000 of the population: All causes	Tuberculosis	Cancer	Resp diseases with influenza	Heart disease	Death-rates per 1000 births: Infant mortality	Maternal mort from childbirth.
Leicester C	242,100	17 3	12 9	1 50	1 31	2 4	0 9	88	4 0
Walsall C B	102,300	22 1	13 6	1 21	0 97	3 4	1 1	115	6 2
Halifax C B	97,860	14 5	16 9	1 20	1 71	3 3	1 9	93	5 6

U D. =Urban district

Leicester

Dr. Killick Millard reports an epidemic of small-pox of the mild type There were 72 cases and no deaths It is now 21 years since the last death from small-pox occurred in Leicester For 40 years Leicester has been preventing small-pox without resort to compulsory infant vaccination There was practically no increase of infant vaccination caused by the epidemic, the total vaccinations for 1925 were 283 and the births 4197 Enteric fever has almost disappeared There were four cases notified and one death There were 26 known cases of encephalitis lethargica, of which 10 ended fatally The number of deaths from cancer (318) was the highest on record

Substantial progress has been made by the corporation in the building of artisans' dwellings, but the need for houses is very acute The most important building scheme is at Aylestone Park, a site of 206 acres, on which it is proposed to erect 1812 houses—1000 of concrete and the remainder of brick. At the end of 1925, 194 had been erected and a much larger number begun Another great housing scheme is on the Braunstone estate (1064 acres), purchased by the corporation for £115,000 Here building operations will begin during 1926 The corporation has made a contract for 1500 concrete houses, subject to optional breaks after the completion of each 500 Two experimental steel houses have been erected by the housing committee and are quite unobjectionable from the point of view of health In spite of the arguments in favour of them—such as the ease of mass production, quick erection, and help for the depressed engineering trade—the committee, after a careful consideration of cost, durability, and upkeep, did not feel able to recommend the erection of this type of house On one of the estates the rents, excluding rates, vary from 7*s* to 8*s* 9*d* for non-parlour houses, and from 9*s* 6*d* to 13*s* for parlour houses On another estate the rates are 8*s* 6*d* for the non-parlour type and 10*s* for the parlour type

The time-limit for black smoke has been reduced from five minutes in the hour to two minutes in the half hour The limit adopted in Sheffield is two minutes for the hour Dr Millard refers to the help to be expected when the new Smoke Bill becomes law The pollution from domestic smoke, however, will still remain, and he thinks that gas committees should offer coke for domestic use on specially favourable terms The clean milk campaign makes progress and measures are being taken to check the sale of

It has further been decided to approach the Government with a view to their taking steps by which the number of club doctors may be still more reduced Government medical officers should, it is suggested, be forbidden club practice, and those only partly engaged in Government work should be made whole-time officers and therefore obliged to give up club practice These measures, however, are likely to be inadequate, because the number of medical men not yet admitted to club practice—such as assistants in hospitals and medical institutions—and the number of students in the last term is so great that the needs of club practice are covered for at least ten years The Hartmann-Bund, together with the clubs, will, therefore, suggest to the Government that it should put an embargo on club practice for ten years They propose that a law shall be passed that medical students who have not finished their first term by April 1st, 1927 cannot be admitted to club practice (Sons and daughters of medical men are to be exempt from this law) If the Government will not agree to the proposal the Hartmann-Bund, either alone or with the clubs, will publish notices on a large scale warning students against continuing the study of medicine and advising school-boys against taking it up

The German Health Office

Fifty years have elapsed since the Imperial Health Office was established, and its jubilee has just been celebrated with great solemnity When Germany became an Empire the care of public health was entrusted to the individual States which form the confederation The difficulty of dealing with epidemics and other problems soon made it necessary, however, for the Central Government to set up an advisory board In the Act establishing the Health Office in 1876 its object was described as follows To advise the Imperial Chancellor on the control of measures taken by individual States for the care of public health and in combating epidemics, to prepare Government Bills dealing with these questions, to give advice on request to the authorities of the individual States, to edit the German Pharmacopœia, and to follow the development of hygiene in foreign countries As the celebrated savants, Virchow and Pettenkofer, declined appointment as president of the new Office, an army medical officer, Dr Struck, was chosen The only members besides the president were Finkelnburg, professor of hygiene at Berlin University, and Roloff, of the Veterinary College, three clerks completed the small staff But as early as 1878 a laboratory of hygiene under Wolfhugel and a chemical laboratory under Sell were added to the equipment Bacteriology was then beginning to play an important part in medicine, and in 1880 Dr Koch, medical officer of health in a small provincial town, was appointed bacteriologist to the Office, because he was known to be one of the few men who at that time had some knowledge of bacteriology His name was soon to become famous all over the world, for in 1882, in the laboratory of the Office, he discovered the tubercle bacillus Working there, also with Koch's methods, his assistants, Loffler and Schutz, discovered the anthrax bacillus, Eberth and Koch the bacillus of enteric fever, Loffler the diphtheria bacillus, and Koch the cholera bacillus Later, in the same laboratory, Schaudinn discovered the *Spirochæta pallida*

The Office is now divided into several departments a chemical department, which deals with the study of drugs and poisons and with the German Pharmacopœia, a medical department, which deals with medical legislation, with the combat against infectious diseases and epidemics, with industrial hygiene, and with medical statistics, a bacteriological department, and a veterinary department The library of the former Army Medical College—which with its 100,000 volumes, is the greatest medical library of the Continent—now belongs to the Office The staff of the Office includes the president, four heads of departments, and 55 scientific members besides the clerical staff There is, moreover, a German Health Council connected with the Office, consisting of 136 members from every part of Germany, who meet to discuss important questions either in full council or in special committees

An Epidemic of Meat Poisoning

In Kalkberge, near Berlin, an epidemic of meat poisoning lately broke out Eighty people became ill with severe vomiting and profuse diarrhœa after eating scraped raw meat bought from a particular butcher in the locality In households where the meat had been cooked nobody was affected It was found on inquiry that the butcher had bought a joint in the central cattle market in Berlin, and that the meat had been examined and passed as healthy Bacteriological examination of the meat, however, revealed infection by Gaertner's bacillus, which belongs to the paratyphoid group, its presence does not influence the appearance of meat, and so the butcher had not discovered that there was anything wrong Seeing that the meat proved healthy in the cattle market, it is possible that the infection took place during its transport It was carried by a butcher's mate in a linen sack from the market to the shop, and it seems probable that either the sack contained bacilli or the butcher's mate was a carrier of bacilli In other localities where pieces of the same joint were sold no case of illness has appeared. Two of the patients have died, the others have recovered The butcher's shop, which was temporarily closed by the district medical officer of health until it had been thoroughly disinfected, has been opened again, as the butcher obviously could not be made responsible for the epidemic

Medical Cinematography

A cinematographic institute for medical purposes has lately been opened in connexion with the Charite Hospital under the auspices of the medical faculty It will be directed by Prof von Rothe, the well known surgeon The apparatus used is carefully sterilised and the camera is fitted up so as to take photographs from the ceiling In this way the various steps of an operation may be made visible, whereas in the ordinary way the patient is hidden from the spectators by the surgeon and his assistants Other rooms of the institute are to be used for filming experiments on animals, epileptic and other fits, the movement of patients, and various pathological conditions

---

IRELAND.

(FROM OUR OWN CORRESPONDENT)

Tuberculosis Officers' Association Annual Meeting

THE annual meeting of the Tuberculosis Officers' Association was held recently in Dublin, and an interesting discussion took place on the problems of tuberculosis in Ireland Dr M Quinlan (Kerry) stated that he knew of several healthy families who were infected, and decimated, by infection introduced from abroad, particularly from America and England, and he suggested that such cases should be refused entry at the ports, or, at the very least, that the Port Medical Authority, if or when established, should report such cases immediately to the responsible authority in the area in which these people proposed to reside Persons emigrating to the United States who contracted tuberculosis within three years of their immigration were deported, and even in the case of American citizens, they were, when all treatment failed, advised "to return to their native air," thereby carrying infection to Ireland Dr O'Beirne agreed and added that when some years ago he was surgeon on a transatlantic liner emigrants were examined before they came on board When they came on board they were again examined by him, and again in the course of the voyage Before they were permitted to land they were, outside the harbour, of skin disease had occurred in the past five years A consignment of apples from Cardiff was found to be excessively contaminated with arsenic and was returned to the importer Overcrowding is general in the town owing to housing shortage. Much good work has been done, however, in the renovation of old property which was rapidly becoming derelict. The 41 wooden houses mentioned in the 1924 report are almost ready The corporation housing estate is nearly built up and a new area of 36 acres is under consideration for housing purposes.

The school report shows a marked improvement in the cleanliness of children Dr. Jean Mackintosh reports on the classes for dull and backward children One of the difficulties the teacher has to contend with is the variation of the age of the pupils In a class of 15 there may be children of three or four different age-groups. These children do not get the advantage of teaching in housewifery and handiwork. and the provision of a special school, not at present financially feasible would be the best solution The eye specialist would like to see myope classes established. and the school dentist complains that 50 per cent of the notices sent out to the parents are entirely ignored Before a dental scheme for school-children can be entirely successful the active coöperation of the teacher is essential

Bilston.

Dr T. Ridley Bailey reports that the industries in his district—iron and steel. tinplate. &c —have no special harmful effect on health. Nearly all the privies in the district have been converted into water-closets There is great need for a destructor, as the four tips give rise to nuisances In the meantime Dr. Bailey urges that the suggestions of the Ministry of Health should be carried out in order to keep the tip nuisance down to a minimum Trouble has been caused by van and shack dwellers on an area of land at Stowheath with no proper water-supply or sanitary accommodation. and dwellings in a deplorable condition. As the result of legal proceedings the area has now been cleared There is much overcrowding and an acute housing shortage The building of houses has not provided for the natural increase of the population and has done nothing to relieve overcrowding Since 1919 the council has built 663 houses The people in most urgent need of houses are unable to pay even the minimum rents. Examples of the rents are given. At an old internment war-camp of huts the weekly rents are 2*s* 3*d* to 4*s* 6*d* For municipal wooden dwellings with three bedrooms the rent is 8*s* 6*d* Other houses built by the council have rents varying from 9*s* 4*d* to 14*s* 6*d* The council has schemes in hand for the erection of 230 more houses There is no antenatal work nor any facilities for orthopædic treatment Last year Dr Bailey congratulated the council on the great progress made in various directions, but he points out that "the continued excessive infantile mortality remains the chief blot in our history" and that overcrowding must be remedied 'before any pride in our work is really justified"

MENTAL HOSPITAL REPORTS

The *Cumberland and Westmorland Mental Hospital* had the low death-rate of 6 9 per cent. during 1925 and a recovery-rate of 26 5 per cent.. which was quite good considering the very small proportion of recent and curable cases admitted The general health was satisfactory. and there were no epidemic diseases except influenza The committee has decided to instal a cinematograph apparatus. which will be very welcome. There is at present no occupation officer and parole is very limited The dentist continues to provide valuable services. The medical superintendent discusses in his report the difficult problem of mental nursing

The seventy-third annual report of the *City of Worcester Mental Hospital at Powick* records a satisfactory year with no epidemic disease save a mild influenza and no cases of colitis A visiting dentist has been appointed and attends fortnightly. and the necessary dental apparatus has been purchased A new main water-supply is being laid down and it is hoped that electricity may shortly be supplied for lighting and power. The recovery-rate was 34 42 per cent. and the death-rate 7 23 per cent. Post-mortem examinations were made on 70 per cent. of the fatal cases Every suitable case among those about to be discharged is sent out first on trial The farm and garden provide occupation for about 14 per cent. of the male inmates, some of whom have allotments of their own

The *City of Cardiff Mental Hospital* has the interesting inclusion of a report from the secretary of the League of Social Service which is in charge of the after-care work. Discharged patients have been visited and helped in various ways and granted allowances clothing or help from appropriate funds The hospital is crowded on the male side and had at the close of the year 570 resident patients General paralysis accounted for 13 58 per cent. of the admissions. but in spite of this there was a recovery-rate of over 40 per cent The death-rate was 8 5 per cent Autopsies were held in all cases where permission could be obtained The percentage of deaths from tuberculosis has steadily decreased during the last five years dropping from 13 5 in 1921 to 9 8 per cent. last year. The visiting dentist examined 515 cases and made 524 extractions during the year as well as scalings and fillings. The aural and gynæcological surgeons have treated 127 and 81 cases respectively and performed 25 minor operations General paralytics were treated by induced malaria; three showed physical but no mental improvement. while four others improved sufficiently for discharge and resumption of work in a subordinate capacity Research has been carried out on the estimation of phosphorus and calcium in the blood plasma and cerebro-spinal fluid and the presence of porphyrin in fæces Eleven nurses passed their final examination The medical superintendent conducts an out-patient clinic at the Royal Infirmary. The visiting commissioner remarks that no one can fail to be impressed by the tremendous effort being made to relieve the patients and to make them as comfortable as their mental state will allow

The *Middlesbrough County Borough Mental Hospital* has 450 patients of whom 66 per cent. are kept usefully employed. The recovery-rate was 42·5 per cent and the death-rate 8 1 per cent. In addition to an epidemic of prevalent influenza there were 23 cases of small-pox in January. but none proved fatal A system of electric lighting has been installed throughout the buildings and the erection of a cinematograph has been begun. There are 30 more cases resident than can properly be accommodated. and there is danger of serious overcrowding There is also need for separate provision for treating new admissions apart from epileptics and sick patients. The visiting dentist does not yet pay weekly visits which limits the value of his work. Seven more nurses have obtained their final certificate, bringing the total to 16 Foot-and-mouth disease was prevalent in the district during the year. but fortunately the measures taken to protect the farm cattle were successful.

The report of the Inspector-General of *Mental Hospitals for New South Wales* records that there are over 8000 insane persons under official cognisance in the State distributed among ten mental hospitals and three licensed houses. There was an increase of 120 in the year ending June. 1925 over the previous 12 months, giving a proportion to the general population of 1 . 275. The general recovery-rate rose by 2 per cent to 42 16 per cent. Over 1000 patients were granted leave or discharged on probation during the year The death-rate was 7 19 per cent . general paralysis accounting for the greater proportion of this figure Roughly one-third of those admitted to the reception houses were discharged. and so were saved the necessity of certification The problem of overcrowding became very grave, and resolute steps dirty milk The report includes photographs of pieces of muslin which have been used for the straining of such milk In one case samples were taken from five churns on delivery, and the outside farmer was fined £10 on each sample, or £50 in all Dr Millard points out that the public may be deceived when they buy bottled milk and that the designation should be clearly shown

Walsall

Dr J A M Clark accounts for the very high infant mortality by epidemics of measles and whooping-cough throughout the greater part of the year Influenza was prevalent in the first quarter and diphtheria excessive throughout the whole year The reorganisation of the medical and nursing services of the corporation has been a great gain in efficiency and economy Much more work has been accomplished in health visiting and school nursing without a numerical increase of the staff Dr Clark points out that much is needed to bring the public health services up to an efficient standard The lack of an efficient isolation hospital hampers work in many ways A maternity home is a real necessity and with it an antenatal clinic At the present time expectant mothers attend one of the centres and are advised by the superintendent health visitor It is most desirable, says Dr Clark, that arrangements should be made at an early date for the regular attendance of an obstetrical expert at this centre

There is room for further developments in the school medical service An orthopædic clinic, already approved, is important, an additional school clinic, also approved, will do much to obviate the great overcrowding at existing clinics More open-air schools are needed The existing open-air school does good work, but it has only accommodation for 60, and there is always a long waiting list Mr Griffiths, the school dentist, reports that there is much scope for educating parents in proper feeding and the requirements of oral hygiene Among the younger children the enamel of the first permanent molars is frequently defective, and Mr Griffiths attributes this to vitamin deficiency during the first two years of life The percentage of acceptance of dental treatment is rising, being as high as 85 in some schools and averaging 62 There are many other sanitary requirements of the borough Unsatisfactory registered slaughter-houses can be closed under the new local Act, but must remain until a public abattoir is provided Out of 19,000 water-closets about half have no flushing cisterns and have to be flushed by buckets, &c There are thousands of large fixed ash-pits which should be replaced by sanitary bins No back-to-back houses or houses without through ventilation have been erected for some 50 years, and the 800 or so of this type which remain are too worn out to repair and should be condemned as soon as the housing scarcity has been relieved Building is proceeding more rapidly and 1053 houses on the two principal housing estates are projected immediately

Halifax

Dr Cyril Banks reports that during the last five years a move has really been made in converting the pail-closets into water-closets During 1925, 1241 were dealt with and there remain to be altered 15,162 in situations where a water-supply and sewer are available The condemnation of the Crossfields area is an important sanitary measure which has received the approval of the Ministry since the close of the year The public water-supply is being extended to suburban districts where the private supplies have been unsatisfactory During the last five years notable progress has been made with regard to smoke abatement Mr Clinch, the chief sanitary inspector, who is an expert in this matter, reports that 182 observations of half an hour each were made, chiefly of chimneys likely to be offenders, and that in 27 cases the limit of two minutes in the half an hour was exceeded In one case a prosecution was undertaken and a fine of £15 imposed Every effort is made to encourage smokeless cooking and heating The gas department supply excellent coke at 25s a ton, and the charge for gas is 2s per 1000 cubic feet There are now nearly 50,000 gas-fire appliances in the 27,000 houses The electricity department also encourages the use of domestic appliances

Premises for a new infant welfare centre have been acquired in Northgate-street The maternity homes in connexion with the Royal Halifax Infirmary and St Luke's Hospital appear to meet the needs of the town, and antenatal clinics are held regularly at both institutions The corporation have arranged to pay to these institutions the cost of maintenance and to recover the money from the patients, but in practice this arrangement has not been greatly used, because the patients have found that it costs them less to go into the infirmary direct than under the corporation's arrangements There were 74 notifications of diphtheria during the year, with 10 deaths Of the 10 fatal cases, 1 died at home and the other 9 died within 24 hours of admission to hospital, the disease being too far advanced for antitoxin to be of any value

West Bromwich

Dr Allan B Hamilton (acting M O H) submits the report, owing to the death of Dr Woolsey Stocks in December, 1925 Although 862 houses have been built by the council during the last five years and 256 by private enterprise, housing conditions still remain bad Not only is the shortage of houses not being overtaken, but the requirements of the increasing population are not even being met Overcrowding shows no signs of improvement The following are some examples given in the report A bedroom measuring 1068 cubic feet occupied by man, wife, and six children, bed-sitting-room occupied for living and sleeping purposes by man, wife, and five children, three families, including 14 persons, occupying a house with two bedrooms, back-to-back house with single bedroom occupied by widow and subtenants consisting of man, wife, son aged 18, and daughters aged 25, 23, 20, and 13, house with single bedroom occupied by man, wife, sons aged 20 and 17, and daughters aged 25, 23, and 12, bed-sitting-room occupied for living and sleeping purposes by man, wife, and five children, the latter all sleeping in one bed Comparing 1919 and 1925 there is an improvement in the general state of repair of dwellings, but owing to the housing shortage the number of persons per house has increased, and the number of houses occupied by more than one family is higher by 50 per cent These figures are based on the examination of 1527 houses which were inspected both in 1919 and 1925 The borough has no sanatorium and the 13 beds retained at other sanatoriums are obviously inadequate

Llanelly

Dr Laurence W Pole submits a very complete report on health conditions in Llanelly, which is one of the chief centres of the tinplate industry, and has doubled in population in the last 40 years Plans have been prepared for a maternity home, and an orthopædic scheme for the children is under consideration Antenatal work began in 1924, 54 expectant mothers attended the centre in that year and 91 in 1925 Beyond giving advice of a general character in regard to food, habits, clothing, &c, no treatment is prescribed The work hitherto undertaken does not therefore appear to be of the nature of preventive obstetrics Much attention has been given to the milk-supply and the bacterial examinations show a considerable improvement during the last three years During 1925, 27 samples came within the Certified standard, 20 within Grade A, and 11 were outside Grade A The average daily consumption of milk per head is only about one-quarter of a pint, and Dr Pole hopes that the improvement in cleanliness will encourage the public to use more milk A curious incident occurred in the summer—namely, the spreading of a rumour that about half the bakers in the town were suffering from bakers' dermatitis The statement was made in public, but inquiry showed that there was no foundation for it and that only eight cases inferior to their own Dr A P. Thomson looks upon rheumatism as a specific infection, the main factors leading up to it are unhygienic conditions associated with poverty and bad housing, and particularly dampness and lack of sunlight It is within his experience that rheumatic children who have had early tonsillectomy are less liable to febrile attacks and heart damage Ultra-violet rays have been found beneficial, though Dr Thompson finds no evidence that this treatment is specific Rheumatic children are often highly strung They are likely to be backward from loss of schooling and may suffer from educational pressure But the experience gained at the Barkerville School shows that with suitable methods they make good progress

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 17TH, 1926

Notifications—The following cases of infectious disease were notified during the week —Small-pox, 157 (last week 128), scarlet fever, 1493, diphtheria, 854, enteric fever, 67, pneumonia, 517, puerperal fever, 49, cerebro-spinal fever, 7, acute poliomyelitis, 8, acute polio-encephalitis, 2, encephalitis lethargica, 17, continued fever, 3 dysentery 13, ophthalmia neonatorum, 110 There were no cases of cholera, plague, or typhus fever notified during the week

Deaths—In the aggregate of great towns, including London, there were 4 (1) deaths from enteric fever, 14 (3) from measles, 6 (3) from scarlet fever, 31 (4) from whooping-cough, 25 (5) from diphtheria, 48 (8) from diarrhœa and enteritis under 2 years of age, and 22 (7) from influenza The figures in parentheses are those for London itself

ROYAL MEDICAL BENEVOLENT FUND

AT the last meeting of the Committee 35 cases were considered and £388 10*s* voted to 25 applicants The following is a summary of some of the cases relieved —

Daughter, aged 56, of M.R.C S Eng, 1858, who practised in London and died this year Assistance is asked for a holiday as the applicant has been in hospital for three months and has undergone two serious operations Voted £10

L.R.C P, aged 76 Owing to age, is unable to get locums although quite fit to undertake the work. Lives with married son, who contributes towards the keep of himself, his wife and the applicant, while the latter is responsible for the rent of 25s a week Applicant's only income consists of the Epsom Pension of £40 and Fund Pension of £26 per annum Special appeal made for help to meet arrears for rent Committee voted £5 Total relief given by the Fund is £82 to March, 1925, elected to an annuity of £26 Jan 1st, 1926

Widow, aged 70, of L S A who practised in London and died in 1897 Has been in domestic service for 15 years and a year ago fell downstairs and broke her wrist She pluckily continued working, but finally had to give up and go into the infirmary where she remained for some months Recently a lady offered her a room rent free but the applicant has to pay something towards her maintenance Fund voted £12 in 12 monthly instalments of £1 each, and an application has been made for the Old Age Pension

Daughter, aged 48 of M.R C S Eng who practised in the Midlands and died in 1910 Her mother died eight months later Applicant started a small business but was induced to sell it so that she could live with and help some relatives Finding that she was not strong enough to do the work she left them, and with the proceeds of the sale went to Australia, hoping that her health would improve She returned home at the end of four months, and has since sold her belongings clothes and jewellery The Charity Organisation Society found her starving in an underground room, gave her temporary help, and referred the case to the Fund, which was able to get her much needed hospital treatment, she is subject to acute asthma and bronchitis and is not strong enough to work She is to go to a convalescent home and the Fund has voted her £26 in 12 monthly instalments of £2 3s 4d each Previous relief amounts to £18

Widow, aged 40, of L R C P Edin who practised in Wales and died in 1923 Left with four children, ages 8 to 18, and with only £100 per annum to support herself and family Son, aged 17, requires help for maintenance whilst studying Voted £3 for three months Previous grants for the same purpose total £29 10s

Daughter aged 27, of M R C S Eng who practised in London and died in 1907 Applicant is confined to bed with heart disease and her only income is £1 a week allowed by an aunt As she requires constant attention a sister gave up a post in Canada to come home and nurse her The Fund is asked to assist towards the expenses Voted £10

Subscriptions may be sent to the Hon Treasurer, Sir Charters Symonds, at 11, Chandos street, London, W 1

THE VALUE OF POPULAR LECTURES

To the Editor of THE LANCET

SIR,—In a paper read at the Jubilee Congress of the Royal Sanitary Institute, Dr W A Daley drew attention to the value of popular lectures as a method of health propaganda Dr Daley both at Blackburn and more recently at Hull has arranged for many such lectures the practical results of which have been exceedingly good Writing from my own experience in giving some thousands of such lectures in recent years, I should like to corroborate every word he said With regard to venereal disease the result of a series of addresses in a town or district where there is a clinic established, but where there has been no popular instruction, is to double and even treble the attendances at the hospital or clinic, and not only that, but it is found of late years, though the number of fresh cases is steadily decreasing, the number of attendances at the treatment centre are very much more numerous, showing that as a result of the instructions given by the lecturers added to the advice of the medical officers, the sufferers have realised that it is necessary to continue treatment even when the first painful and unpleasant symptoms have subsided This, of course, is extremely satisfactory

I have found also that lectures to the fathers and mothers of school-children, and to women attending maternity and child welfare centres, lead to an appreciable increase in the number of expectant mothers seeking that antenatal advice and treatment which is so conducive to future good health The scientific and physiological facts of athletic sports and strenuous games have after many years begun to receive that attention which has long been their due Popular lectures on the Physiology of Motion, and the rudiments of getting and remaining "fit," and the "re-creation" of the body by games and proper physical exercises, are now frequently demanded by boy scoutmasters, girl guiders, teachers in elementary and other schools, as well as experienced athletes I find such lectures followed with the greatest attention, and they give rise to any number of intelligent questions from the audience

Dr Daley remarks on the difficulty of getting enough medical lecturers to carry on this sort of work There are two things essential to make such lectures go down well The first that the lecturer should be heard, and the second that what is heard is adapted and suited to those who hear it A well-organised free film showing is a great asset in attracting a suitable audience, and it is wise to give the lecture and explain the film as far as may be required before showing it I most cordially agree with what Dr. Daley says about the value of addresses to clubs, brotherhoods, and such like organised gatherings The members are intelligent and spread the light in their districts The recent regulations of the Ministry of Health will largely help those local authorities who may wish to make use of these valuable methods of instruction in health matters under the ægis of their medical officers of health

I am Sir, yours faithfully,

London, July 26th, 1926 E B TURNER

THE STUDY OF EPILEPSY.

To the Editor of THE LANCET

SIR,—The American National Association for the Study of Epilepsy as a part of the Ligue Internationale contre l'Epilepsie is anxious to promote a gathering and closer union of those neurologists and psychiatrists of all nations who are interested in the broad field of epilepsy and convulsive diseases were taken to deal with it by the erection of several new wards, while an entirely new hospital is shortly to be built to cope with the steady increase in the numbers of mental patients There is still urgent need, however, for accommodation for the criminal insane, many of whom are now improperly retained in gaols There is a psychiatric clinic, with accommodation for 132 uncertified patients, working in harmony with the out-patient department at the local hospital The fact that its work has far outgrown the available accommodation shows that legislation is needed to permit the ordinary mental hospitals to accept voluntary boarders As a matter of fact there are voluntary boarders in all the hospitals, but the procedure has not been regularised Still more urgent is the need for a Mental Defectives Act since New South Wales has failed so far to follow the example of other English-speaking countries in providing for the education and segregation of these cases As the report observes, the situation is serious, for the mental and physical standard of the race is involved

SCHOOL MEDICAL SERVICE

The following table summarises the figures given in the school reports for two county areas and one city .—

Name of district	No on roll	Average elem school attendance	No of routine examinations	No of special examinations and re-inspections	Percentage of children found on routine examination requiring treatment †
West Riding of Yorkshire	194,683	—*	67,079	13,924	27 54
Bedfordshire	—*	—*	5,087	1,812	22 03
Birmingham	—*	—*	39,216	66,243	26 04

* Not given † Excluding dental defects and uncleanliness

West Riding of Yorkshire

Although steady progress has been made in ascertainment and treatment, Dr J R Kaye maintains that "much of the labour involved should be prevented if child-welfare work assumed greater proportion and the ideals of prevention of ailments and promotion of health were kept more in view" The keynote of his stimulating report is his belief that "the index of efficiency in school medical work is the number and quality of the special inquiries made"

In reviewing some of the special inquiries made by the staff on regional peculiarities, Dr Kaye sums up "The sturdy independence and self-reliance of the textile workers is in the direct line of the best Yorkshire tradition This independent attitude stands in bold contrast to that of the mining population who wait to have everything done for nothing" Although the wages in the mining districts and the textile areas are comparable, the children in the mining districts are neither as clean nor as well fed as those in the textile areas—unfortunately, the latter have recently shown some falling away in general condition owing to unemployment Local inquiries have shown inadequate and ill-balanced dietary in many of the districts, and Dr Kaye joins voice with the many medical officers who call for the systematic teaching of food values and the inclusion of simple dietetics in the school curriculum Hygiene must not only be taught but practised in the school, and to keep windows closed so as to keep up the temperature is as reprehensible to Dr Kaye as was the excuse given for the absence of soap in a lavatory—that it might be stolen Much praise and encouragement is given to the teachers who have established open-air classes, and attention is drawn to the excellent experiment in one area in arranging for children from overcrowded homes to sleep in tents under the supervision of teachers The problem of accommodating the abnormal children is acute in most rural districts and the West Riding is no exception—there are 562 delicate children attending elementary schools and 1023 at no school; 307 feeble-minded children are in attendance at ordinary elementary schools, whilst 202 receive no training and presumably little supervision

Bedfordshire

Dr R T Herdman reports that during 1925 there was a severe epidemic of mumps and influenza which lowered the general health of the children in the county In some areas measles and whooping cough were also prevalent and consequently there was a drop in the average attendance But in spite of the lowered condition of the children, the height and weight of entrants and leavers is markedly better than that of pre-war children Entrants during 1925 are on the average nearly 1 inch taller and 1 lb heavier than the average pre-war child of the same age Following the long journey to school, many of the children in the county arrive with wet feet and stockings, this lowers their vitality and is especially bad for rheumatic conditions Dr Herdman suggests that a spare pair of stockings and shoes should be kept in the school for each child A simple pattern of felt slippers could be made by the elder girls In reviewing medical inspection since it was started in 1908, Dr Herdman traces the rise of parental interest and the increasing help of teachers and interested laymen In 1909 79 per cent of those examined required treatment, which, according to Prof Kenwood, compared favourably with the rest of the country In 1925 only 22 per cent required treatment Coincident with this decrease in the percentage requiring treatment, there has been a steady increase in the percentage of those obtaining it—from under 40 per cent in 1909 to over 70 per cent in 1925 The defect showing the highest incidence was anæmia (416), followed by defective vision and squint (256), and then debility (defective nutrition) 239 This rather indicates that the children in Bedfordshire are not in such good general health as are the children in many of the large urban districts

Birmingham

Dr G A Auden's report is of outstanding interest; efficiency and enthusiasm are shown alike in the close ascertainment of defective and exceptional children and in the provision made for them The total sum of the treatment undertaken by the school medical staff is comparable to that of a fair-sized general hospital Mr F B. Gilhespy, the aural surgeon, has interesting things to say about mastoid operations, and of his own cases 75 per cent promise favourable results A useful comparison is made between the condition of the teeth of children in Birmingham and in New Zealand The proportion of perfect sets of teeth in Birmingham between the ages of 14 and 16 is 60 times as great as in New Zealand Whilst the nutritional and hygienic standards are higher in New Zealand, these factors are outweighed by the influences of more eating between meals and the greater consumption of confectionery Dr Auden insists that cripples will exist as long as the causes of deformity remain, and that it is practicable to prevent the conditions that produce the cripple Much has already been done in Birmingham by open-air and physical deficiency schools and by remedial exercise clinics, and this year there will be a new clinic for massage and electrical treatment Dr Elizabeth Moffett, reporting on hypermetropic children, states that there is great improvement in their school work after wearing appropriate glasses for a short time—probably the strain of focusing near work is too great for the less robust These observations may in part explain the difficulty which many children of apparently normal intelligence find in learning to read and write

In a close analysis of 69 cases of encephalitis lethargica Dr Auden argues that special provision for these cases is a pressing need Their intellectual capacity is rarely sufficiently reduced to make them certifiable as mentally defective, and they are unsuitable to mix with those whose intelligence is much unconscious, cyanosed, eyes bulging, pulse 150, very weak and filiform, respirations hurried and stertorous, temperature subnormal, pupils much dilated, corneal, conjunctival and cutaneous reflexes wholly absent I injected cardiac stimulants, and in an hour's time she began to improve—pulse became stronger and slower, respirations easier, cyanosis began to fade out, superficial reflexes reappeared On Feb 17th the general condition was good, but she was completely unconscious save when, from time to time, she would cry from severe headache. I made a lumbar puncture. Fluid came out under high pressure, bloody-red, but with no clots I removed about 50 c.cm At once the patient looked relieved, and began to speak some intelligible words. On the 18th she was more or less conscious, and after a week she came to see me enjoying very good health

I hope these details are of sufficient interest to warrant space being given to them.

I am, Sir, yours faithfully,
H. SHEHADEH, M D.

Beirut, Syria

TUBERCULOSIS IN THE SHETLAND ISLANDS.

To the Editor of THE LANCET

SIR—In your issue of July 10th Dr. Willoughby raises a very interesting point in regard to the ætiology of tuberculosis and one that does not seem to have attracted sufficient attention The comparatively high rate of tuberculosis infection in the Shetland Islands is to my mind what is not unusual in districts or countries where the native cattle enjoy comparative freedom from tuberculosis Is this not true of Japan where bovine tuberculosis is of comparatively recent introduction?—and what about India, where a large proportion of the native population do not drink cows' milk? Is tuberculosis any less in these countries than it is here? One must remember that other factors—dietetic hygienic. historical—come into play, and any investigation on the lines suggested by Dr Willoughby would have to take these into consideration

Again is it not a fact that the clinical type of tuberculosis seen in the bovine-free areas is of a more virulent type? I happen to see a good few cases from the Shetlands and some of the northern counties and western isles and comparatively few of them recover under treatment. The specific resistance of the individual affected is poor and the disease usually runs an acute course with a fatal termination The good old fibroid type is certainly less in evidence than in the more populous areas farther south That might partly be due to the fact that tuberculosis has not been with the Shetlanders so long as with us further south But taking all these factors into consideration. one must admit that your correspondent's suggestion that "the ingestion of constant submorbific doses" of the bovine type of tubercle bacilli does play its part in conferring some immunity "in counteraction of the human type of the disease" is a valuable one and worthy of full investigation

I am. Sir yours faithfully
FELIX SAVY

The Grampian Sanatorium, Kingussie July 27th, 1926

THE LATE DR R E HORSLEY—Dr Reginald Ernest Horsley who has died at the age of 63 was the son of Captain Charles Horsley, of the East India Company's Service. Born at Sydney, New South Wales, he was educated at Sydney Grammar School, Trinity College, Dublin and the Universities of Melbourne and Edinburgh, and Berlin Graduating in medicine at Edinburgh in 1885, he served for some time as secretary to the scientific staff of the *Challenger* Expedition Commission In 1890 he became F R C S Edin. and three years later M D Devoting his attention to ear nose, and throat work he held appointments as clinical assistant at the Royal Infirmary and surgeon to the Edinburgh Ear and Throat Dispensary. In 1890 he was secretary to the Section of Otology at the International Medical Congress at Berlin For some time Dr. Horsley was physician to Stonyhurst College but in 1903 he retired from practice in order to give his whole time to literary work he published several novels and books of travel and adventure Settling eventually at Crail he became a magistrate and later provost of that royal burgh—an office which made him Admiral of the Forth Dr Horsley married Mary, daughter of the late Mr William Inglis, of Kirkmay

HOUSE OF LORDS.

THURSDAY, JULY 22ND

Mental Deficiency Bill.

Viscount GAGE, Lord-in-Waiting. in moving the second reading of the Mental Deficiency Bill, said the most important provision was in Clause 1, where the definition of a mentally defective person was altered and extended to include persons affected by injury or disease since birth or early age. There was a difference between mental deficiency and lunacy. The latter was caused by a general breakdown of the normal faculties, but in the case of a mentally deficient person there was actually some physical defect in the brain. Naturally, therefore, the majority of these cases occurred either at birth or by development at an early stage of the individual's life There were cases where some injury or disease, particularly the disease known as encephalitis lethargica, produced a condition analogous to innate mental deficiency Under the existing definition it was impossible to certify these individuals as mental defectives owing to the inclusion of the words "from birth or from early age." Under this Bill this would be remedied, and these persons would be able to be attended to in a proper kind of mental home There were certain other amendments made in the original Act of 1913

The next most important provision occurred in Clause 6. Subsection (1) of that clause provided that a local authority might build a larger institution that it required and take cases by contract from other local authorities An institution for from 500 to 1000 places was more efficient as well as more economical than a smaller institution and some of the smaller local authorities would themselves need an institution containing this number of beds Subsection (2) of this clause contained provisions allowing the local education authority and the mental deficiency authority—both committees of the one council—to provide a joint institution should they deem that desirable This clause had the approval of the Board of Education. The remaining clauses of the Bill merely made small administrative changes which had been found desirable. The Bill had been very thoroughly investigated by a committee on which all the leading specialists on the subject were represented as well as the medical Members of the House of Commons, and he understood that it had their entire approval.

The Bill was read a second time.

On Monday, July 26th the Mental Deficiency Bill passed through Committee and was reported to the House without amendment.

On Tuesday July 27th, the Mental Deficiency Bill was read a third time and passed

HOUSE OF COMMONS

WEDNESDAY, JULY 21ST

London Doctor and the Telephone Directory

Mr MACKENZIE LIVINGSTONE asked the Postmaster-General whether he was aware that Dr A. E. W. Idris, practising as an anæsthetist in London had suffered loss in consequence of his name having been negligently omitted from the London Telephone Directory for October. 1925; and what steps he proposed to take to compensate this gentleman.—Viscount WOLMER (Assistant Postmaster-General) replied: I am aware that through an unfortunate error which I greatly regret, Mrs. Idris s name was inserted in the London Telephone Directory for October, 1925, instead of Dr Idris's. One of the conditions relating to entries in the Telephone Directory is that the subscriber shall have no claim against the Post Office in respect of any omission or error and in the circumstances I am not able to grant compensation to Dr Idris. I have however, offered to bear the cost he had incurred in notifying the error to a number of his clients but this has been refused by Dr Idris.

THURSDAY JULY 22ND

BOARD OF EDUCATION VOTE.

The House went into Committee of Supply on the Civil Service Estimates for 1926–27

On a vote of £28,300 000 for the salaries and expenses of the Board of Education,

Lord EUSTACE PERCY. President of the Board of Education, said that the Board was continuing to reduce the size of the classes in the elementary schools On March 31st 1924, there were 24 972 classes with over 50 children on the roll. These figures related to children on the roll and not average attendances. They did not mean that actually 50 children were being taught in all these classes, but that 50 children

I have been appointed delegate by the National Association for the Study of Epilepsy to attend the sessions of the Gesellschaft deutscher Nervenarzte in Dusseldorf in September, and shall be in Europe during that month, hoping to get into contact with all workers in this field Communications from those who are interested should be addressed to me at the Psychiatric Clinic, Nussbaumstr 7, Munich, Germany.

I am, Sir, yours faithfully,

OTTO WUTH,

Associate in Psychiatry of the Johns Hopkins Hospital and University and A O Professor of Psychiatry in the University of Munich

Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore, July 15th, 1926

JOINT ACTION

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LTD , AND THE MEDICAL DEFENCE UNION, LTD

To the Editor of THE LANCET

SIR,—The Councils of the Medical Defence Union, Ltd , and the London and Counties Medical Protection Society, Ltd , have agreed that each Society will defend a member in an action arising out of the acts or omissions of an assistant or locum tenens, who is a member of the other Society, as if the assistant were a member of the same Society as the principal, and similarly in the case of actions against members on the staff of hospitals against whom actions are brought arising out of the acts or omissions of duly appointed subordinate medical officers

We are, Sir, yours faithfully,

HUGH WOODS,
General Secretary,
London and Counties Medical Protection Society, Ltd ,
Victory House, Leicester square, W C

JAMES NEAL,
General Secretary,
Medical Defence Union, Ltd
49, Bedford square, W

IMMUNITY AND MALIGNANT TUMOURS

To the Editor of THE LANCET

SIR,—With reference to the paper by Dr Thomas Lumsden in THE LANCET of July 17 on the above subject, in which he describes cytolytic effects in vitro on mouse tumour and curative results in rat sarcoma by means of antisera of animals inoculated repeatedly with cancer tissue of another species, may I point out that the method is not new In 1912 the late Dr Carrington Purvis (Grahamstown) used serum obtained from sheep, which he had inoculated several times with specially prepared human cancerous tissue His object was to obtain " a cytolitic serum which would kill the cells of cancer occurring in a human being " He thought that he obtained necrosis in a large epithelioma of the face in a patient under his care by subcutaneous injections of the inoculated sheep serum In the same year I inoculated rats repeatedly with mouse tumour, and the sheep, goat, and rabbit repeatedly with fresh human mammary cancer tissue I inoculated sheep repeatedly with human cancer serum also In all cases the reactions of the blood-serum of these animals, after repeated inoculation, were found to run parallel with reactions I had obtained previously with antidiphtheritic serum and other immune sera, and in a recurrent operative advanced abdominal case of cancer treated with the inoculated sheep serum it was thought improvement followed The results of my experiments in 1912 were given in a paper before the International Congress of Medicine held in London in 1913 In August, 1924, I repeated the inoculation experiments in the sheep at the Brown Institution with results which fully confirmed my earlier ones In my letter to THE LANCET, which you published on March 14th, 1925, I drew attention to these facts, and noted that the sheep is more responsive to inoculation than the rat, rabbit, and goat At the same time the question arose as to whether the horse might be a more suitable donor, as in the usual preparation of antidiphtheritic serum In his present paper Dr Lumsden states that " an antiserum made by inoculating human mammary cancer into sheep kills mouse tumour cells in vitro practically instantaneously." He goes on to say that the antiserum is *non-toxic* to other normal mouse tissues, and, in short, " perhaps the most specifically anti-malignant of all the sera tested is the antiserum obtained from a sheep which has been repeatedly inoculated with human mammary cancer and human breast tissue "

No reference is made to the work of Purvis and mine by Dr Lumsden, whose work is considered new by the lay Press —I am, Sir, yours faithfully,

J A SHAW-MACKENZIE, M D Lond

London, W , July 22nd, 1926

A LARGE DOSE OF ASPIRIN

To the Editor of THE LANCET

SIR,—The following seems worth recording

A healthy woman, aged 35, with no history of alcoholism, commenced to drink brandy very heavily and continued to do so for three weeks On the day I was called to her she had consumed the contents of a bottle of brandy between 8 A.M. and noon, and had also taken the contents of a large bottle of hair-wash labelled eau-de-quinine, popularly believed to be an excellent emmenagogue About 3 P M she took in one dose 485 gr of aspirin in tablet form Two hours later she vomited copiously, and I saw her about 5 30 P M Her face was cyanosed, respiration 40, pulsus alternans, and complaining of " air-hunger " No active treatment was adopted, she was placed under constant observation and quickly recovered, showing during recovery slight œdema of the face and complaining of very severe headache —I am, Sir, yours faithfully,

J HARGREAVES ROBINSON

Harley street, W , July 25th, 1926

SUBDURAL HÆMORRHAGE

To the Editor of THE LANCET

SIR,—The recording in THE LANCET of May 22nd of cases of toxic subdural hæmorrhage by Mr A. G Banks and Dr A M N Pringle prompts the publication of the following two cases

CASE 1 —On April 15th, 1923, I was called to see a male patient, strong, aged 50, married, but no children, who told me that two days previously he went to bed at 10 P M. as well as usual, but about 12 P M. was awakened by an unbearable attack of pain in the back of the head, heaviness in the eyelids that prevented him from opening his eyes, and dyspnœa A doctor prescribed sedative cachets during the next day, but they were of no avail On examination the patient showed a normal temperature, pulse, and respiration, and no sign of new paralysis (he had suffered from paraplegia from infancy) but could not open his eyes on account, he said, of heaviness Severe headache and pupils somewhat dilated. I suspected subdural hæmorrhage and advised lumbar puncture, but could not obtain his wife's permission A second opinion was obtained, and my colleague advised a bacteriological examination of the blood and cerebro-spinal fluid In the evening I received a report that there were no malarial parasites in the blood On puncture cerebro spinal fluid came out under pressure A request followed from the patient to " come and puncture him," because the small quantity of fluid removed had relieved his headache very much I removed about 40 c cm. of bloody fluid The headache was almost completely relieved I visited him on the 17th His eyes were open, but he noticed that the field of vision in his left eye was contracted On the 18th I punctured him again and took out about 30 c cm of fluid, but this time it was colourless The general condition of the patient improved, and the headache disappeared To day—more than three years later—the patient is in perfect health, but the field of vision in the left eye is still contracted

CASE 2 —On Feb 16th, 1924, a woman came to me for a severe attack of pain in the lower part of the head Before I saw her another doctor had prescribed her some sedative cachets, of which she swallowed one When a few yards from the pharmacy she felt very weak and entered the house of a friend to get rested She remained there about an hour, and then got ready to go home, but suddenly fell on the floor unconscious Her face became cyanosed, respiration stertorous The doctor who had prescribed the cachets ordered stimulant and gave a bad prognosis When I was summoned I found a patient, aged about 40, well built,

Injured Workmen and Hospital Treatment

Mr NEIL MACLEAN asked the Under Secretary to the Scottish Board of Health whether he was aware that John Welsh, senior, valve-shaft camp, and John Welsh, junior, intake ii camp at Balfour and Beattie's Contract, at Fort William, were both injured at work, one suffering from head injuries and the other suffering from a fracture of leg at ankle, that both these men were under treatment at the company's hospital at Fersil Camp and were both ordered to leave the hospital on July 5th, that they were again ordered to leave the following morning, that the company having refused the request of their panel doctor to accommodate the men, he (the panel doctor) sent them to the Belford Hospital, Fort William, that night, that these injured men were refused admittance to the hospital and had to lie out all night, and that all the men on the contract had deductions taken from their wages for this hospital, and whether he could state upon whose orders they were ejected from the Fersil Camp Hospital, and who gave the instructions that they were to be refused admittance to the Belford Hospital, Fort William.—Major ELLIOT replied There seems to be some confusion concerning these cases John Welsh, aged 26, was injured as long ago as April 14th, remained for four weeks in bed at Fersil Camp Hospital, and for two weeks on crutches On July 7th, after being for 12 weeks under treatment, he was seen by the compensation officer, who stated he was fit for light duty He did not accept the position, and after a further six days accommodation at Base Camp was sent by his panel doctor to the Belford Hospital, where, after examination by the medical superintendent, he was informed that the case was not one for hospital treatment, and was accordingly not admitted The medical superintendent's report is that the original injury was not a fracture, but a severe sprain and that recovery would be assisted by light exercise The other case of John Welsh is that of a man who received a head injury on May 31st There was no evidence of fracture, but simply of scalp injury He was removed on July 7th to Base Camp as not being further in need of hospital treatment He remained at Base Camp until July 13th without being asked to do any duty. He left to see his panel doctor, who in this case also sent him to the Belford Hospital After examination by the superintendent he was not admitted as not being in need of hospital treatment I understand that contribution to the Belford Hospital is on a voluntary basis and that some men pay and some do not With regard to the last two parts of the question I have not yet specifically ascertained on whose instructions these men were dismissed from Fersil Hospital The refusal of admission to Belford Hospital was given as part of his duty by the medical superintendent of the hospital

Dairy Cows in Great Britain and Other Countries

Mr ROBERT WILSON asked the Minister of Agriculture the proportion of milk-producing cows to the population in Great Britain, with comparative figures in other countries for which statistics were available —Mr GUINNESS replied The number of dairy cattle per 100 of the population in the undermentioned countries, subject to difference of definition and classification, is as follows —

Country	Population	Year	No of dairy cattle	Year	No of dairy cattle per 100 of population
Great Britain	43,783,000	1925	3,163 523	1925	7 2
Irish Free State	3,163,000	1925	1,264,368	1925	40 0
France	39,310 000	1922	7,303,940	1923	18 6
Germany	62,642,000	1924	9,723,238	1924	15 5
Holland	6,977,445	1921	1,085,713	1921	15 6
Belgium	7,744,259	1924	839,076	1924	10 8
Denmark	3,377 000	1924	1,368 548	1924	40 5
Rumania	16,750 000	1923	2 426,233	1923	14 5
U S A	112,078,611	1924	22,255,000	1924	19 9
Canada	9 226 740	1924	3,726 985	1924	40 4
Australia	5 873,503	1924	2 304 644	1923–24	39 2
New Zealand	1,384,130	1924	1,292,286	1924	93 4

Note —The figures for foreign countries have been taken from the latest Year Book of the International Agricultural Institute and from the official publications of the countries concerned

MONDAY, JULY 26TH

Medical Services in Windward and Leeward Islands

Mr HURD asked the Secretary of State for the Colonies whether he had received information from the Windward and Leeward Islands that their steamship communications with the outside world were now restricted to a single unpunctual monthly freighter without cold-storage capacity, and whether, as this isolation was affecting the school and medical necessities of the islands, remedial measures could be taken through the Imperial Economic Committee, or in any other way —Mr AMERY replied I am aware that the subsidised steamship service hitherto operated by the Royal Mail Steam Packet Company between Canada and the Colonies mentioned has been withdrawn and replaced by a service of the nature indicated The question was considered by the recent West Indian Conference and a resolution passed by that conference has been transmitted to the Government of Canada As my hon friend is aware, the agreement concluded at Ottawa in 1925 between the Government of Canada and the governments of the West Indian and other colonies provided in Article IX for steamship services to the Windward and Leeward Islands, and pending the establishment of such services I do not consider that there is any further action which I could usefully take in the matter

Out-relief to Miners' Families in Lichfield

Mr ARTHUR GREENWOOD asked the Minister of Health whether he had received any communication regarding the conclusions reached by the Lichfield Board of Guardians at its meeting on Friday, July 23rd, on the question of the continuance or non-continuance of out-relief for miners' wives and children —Sir KINGSLEY WOOD replied. Yes, Sir My right hon friend is informed that the guardians resolved to continue to relieve the wives and children of strikers He is taking steps to obtain further information

TUESDAY, JULY 27TH

Pay of the Royal Army Medical Corps

Sir PHILIP RICHARDSON asked the Secretary of State for War whether the Warren Fisher Committee on the pay of the R A M C had now made a report; when it was proposed to revise the pay, and from what date —Sir L WORTHINGTON-EVANS replied The answer to the first part of the question is in the affirmative, as will be seen by reference to the answer given by my right hon friend the Prime Minister on June 15th As regards the remainder of the question, the revised rates of pay, which have already been announced in Army Order 196 of 1926, took effect as from July 1st

Hospital Treatment of Scottish Workmen.

Mr. NEIL MACLEAN asked the Under Secretary to the Scottish Board of Health by whose instructions the camp commandant at Fersil Camp ordered two men, both named John Welsh, and suffering from injuries received at work, to leave the camp hospital late on July 5th, and again at breakfast on July 6th, whether these instructions were issued from the offices of the firm at Fort William, and whether the company provided any conveyance to take these men to Fort William, 25 miles distant —Major ELLIOT replied I am informed that the instructions were given by the company's headquarters office at Fort William and that the men were conveyed there by the company's train.

Food and Drugs Legislation

Major Sir GRANVILLE WHELER asked the Prime Minister whether he could give facilities for the passing of the Sale of Food and Drugs Act (1875) Amendment Bill during the present session.—Mr BALDWIN replied I regret that I see no prospect of time being found for this Bill, but I would remind my hon. and gallant friend that the Bill which was introduced by Brig-Gen Clifton Brown has been dropped

Approved Societies and Dental Committee's Findings

Mr HORE-BELISHA asked the Minister of Health whether the findings of the Dental Committee would be submitted to each approved society for consideration before any action was taken thereon —Sir KINGSLEY WOOD replied Any agreement which may be arrived at as the result of the discussions now in progress between representatives of the approved societies and of the dental profession will be submitted before any action is taken thereon to the Consultative Council on Approved Societies' Work, which is the recognised statutory body representative of approved societies

---

THE LATE DR E W SEYMOUR —Dr Edgar William Seymour, M V O, who has died at Cowes at the age of 58, was educated at Cambridge and St Bartholomew's Hospital graduating in medicine in 1893 Like his father and grandfather before him, he was attached to the Royal household at Osborne, being appointed Surgeon Apothecary to Queen Victoria and Surgeon in Ordinary to Princess Beatrice He was also surgeon to the Royal Yacht Squadron and consulting physician to the Royal Convalescent Home for Officers, Osborne, but retired from practice some years ago were on the roll On March 31st, 1925, there were 21,345 such classes, or a reduction of more than 3600 The figures for March 31st, 1926, were not yet available, but on that date, compared with March 31st, 1925, there were 17,000 more children in average attendance and, on the other hand, they had 1129 more teachers These figures meant that on March 31st, 1925, 14 per cent of all the classes in the elementary schools in England and Wales had over 50 children on the roll, 56 per cent had not more than 40 children on the roll, and 28 per cent had not more than 30 on the roll The question of buildings and accommodation was the main problem that they had to consider at the present moment They had schools on what were called the black lists, with something over 500,000 children at present on the roll Of these, 27 per cent were council schools and about 73 per cent were voluntary schools Of 219 council schools on Black List A, 65, or about 30 per cent, had already been dealt with by proposals contained in the revised forecasts for this year, and these forecasts also provided for 30 more schools to be built by local authorities which would take the place of black-listed voluntary schools The programmes gave every hope that they would have tackled this part of their problem completely, or more or less completely, by 1930 The total amount of elementary school buildings provided for in the revised forecast leaving out building proposals which had been dropped this year, was 244 new schools and 111 enlargements—a very large programme The progress in regard to the voluntary schools had not been so great Some 21 voluntary schools had been removed from Black List A since the original estimates were prepared and 30 more were being dealt with by local authorities this year, making a total of 51, or about 10 per cent of the total number of voluntary schools on Black List A

Mr **TREVELYAN** moved to reduce the vote by £100 He said that a great many of them were extraordinarily uneasy about the policy being pursued by the President of the Board of Education The Government were in financial difficulties and the President of the Board had found it necessary to have a year or two of delay and reaction, and they were told that they would have to wait for a revival of trade The Labour Party challenged the whole position that educational expenditure ought to depend in any sense upon the general condition of the trade of the country When good times came, if ever they did recur, they would not be able by the expenditure of money to improvise an educated generation of the children who were now losing educational advantages They were inclined to say that in times like these, when the gulf between the rich and the poor was greater, that was the time when the nation ought to try to bring the two closer together by providing national education

Mr **HARRIS** said that a matter which had been omitted from the statement of the President of the Board was the provision of special schools There was nothing more pathetic in the great cities than the large number of mentally defective and physically defective children It was one of the curses of civilised life, of overcrowded streets, and bad housing that they seemed to breed these puny, miserable, mentally starved children In London they had done great work in giving these children a chance by giving them an extra two years in special schools Not only in that way did they give a chance to the child, but they saved the State in the long run, because these children, instead of becoming a charge on the State, became in nine cases out of ten breadwinners and able to earn their own living There was still a very large number of areas in which no provision whatever was made in the way of special schools Twenty-seven county authorities and 102 non-county authorities made no provision for special schools He knew that the President was conscious of this deficiency He was all for economy and against waste, but for God s sake do not let them economise at the expense of these unfortunate children Do not let them hold up their training while the Board was inquiring as to some ideal method They knew that the Chancellor of the Exchequer was a hard nut to crack, but if the President would see that he was provided with the necessary funds to enable local authorities to carry out their duties he could be assured of the support of all parties in the House

Dr **HADEN GUEST** said we were no longer a nation ruled by a governing class, by people equipped however effectively up to a certain limit at the public schools We were a nation ruled by an immense democratic many-headed majority, and unless that democracy was really well educated in the best sense of the word we should not be able to solve the tasks that were facing us He would be glad if they could get a real improvement in the general health of the population A general improvement in the standard had been going on, although there had been a reaction in the last year or two Probably, however, they would be able to get over that. If they could get a really high level of health and a really national system of education, which would put all to a certain extent on the same level, he believed that the nation would be able to solve its problems If they were to have in the nation a common mind and the possibility of all coöperating together, they must have a common background in the minds of the children of the nation.

The Duchess of **ATHOLL**, Parliamentary Secretary to the Board of Education, replying to the points raised in the debate, said that if hon Members would look at the estimates they would see that the capital expenditure approved by the Board last year was higher in the case of elementary, secondary, special, and medical services than in any year since the war Therefore the Board was not standing still. There had been a steady advance in special services, and there were 3800 more special school places than previously It was impossible to ignore the state of trade, but they must get the best possible value by organisation as well as by the quality of the teaching If in time of great financial difficulty they were able not only to hold their ground, but make an appreciable and steady advance in essentials and in laying their foundation, they hoped to see a far better structure erected and possibly make an all round advance in the progress of education

The motion to reduce the vote was negatived by 221 votes to 97

Government and Nursing Home Report

Mr **CAMPBELL** asked the Minister of Health whether the Government proposed to adopt the report of the Select Committee on Nursing Homes, and whether he was aware of the urgency of action which was needed in this respect to meet the condition of less well-off middle-class families —Mr **NEVILLE CHAMBERLAIN** replied There has not yet been time for the Government to consider the report and I am accordingly unable to make any statement on the first part of the question The second part of the question does not appear to arise out of the report, and I can only say that there are in any case no funds at my disposal enabling me to meet what I understand to be the object of my hon. friend

Rehousing Schemes in Insanitary Areas

Mr **CAMPBELL** asked the Minister of Health whether he would state the attitude of his department towards the policy of erecting blocks of tenement dwellings to provide alternative accommodation for those people now crowded into insanitary areas, and whether, if his department approved the policy, he proposed to recommend its consideration to the different local authorities —Mr **NEVILLE CHAMBERLAIN** replied Where proposals for clearing insanitary property are approved it is the practice of my department to require that provision shall be made for rehousing the persons to be displaced The precise form of the provision will depend on the circumstances of the particular case While I think the working-classes can generally be housed better in cottages than in blocks of tenements, there are certainly cases in which it is necessary to adopt the latter form of accommodation, and in such cases the erection of tenements would be sanctioned

Indian Medical Service and Free Passages

Colonel **DAY** asked the Under Secretary of State for India if his attention had been drawn to the disappointment expressed by the Indian members of the Indian Medical Services at the concession of free passages to Europe and back lately granted to European members of the Indian Medical Service, which had not been extended to include Indian members, and, with a view to establishing and maintaining the standard of prevailing knowledge and efficiency, would he consider recommending the extension of travelling facilities being afforded Indian members —Earl **WINTERTON** replied My noble friend has received and considered memorials from Indian members of the Indian Medical Service on this subject, but he has found it necessary to maintain the principle on which the leave passage concessions are confined to officers of non-Asiatic domicile The claims of the Indian members of the service, so far as they relate to facilities for study, are receiving further consideration

Slum Clearances in Southwark

Colonel **DAY** asked the Minister of Health the number of dwellings to be proceeded with by the London County Council on the Tabard-street, Southwark, clearance and rebuilding scheme, the number of such dwellings that had been completed, and when it might be expected that the remainder would be completed —Mr **NEVILLE CHAMBERLAIN** replied The Order confirming the scheme to which the hon Member refers required the provision of rehousing accommodation for 2580 persons, and accommodation has already been provided for 2388 persons in 121 tenement dwellings erected on the area By an amending Order, dated July 10th last, the number of persons to be rehoused was increased by 1000, and I think that the hon Member may be assured that no time will be lost by the London County Council in completing the amended scheme

ST THOMAS'S HOSPITAL OLD STUDENTS' DINNER.—This dinner will be held on Friday, Oct 29th, at the Hotel Victoria, Northumberland-avenue, W C, at 7 for 7 30 P M Dr R Percy Smith will take the chair

IN a list just issued are recorded the names, appointments, and degrees of old students of St Thomas's Hospital. The names are also classified under place of residence, and particulars are given of the times of attendance of members of the staff, together with telephone numbers and other details which will be found useful by those who have to do with the hospital.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL—A new operating theatre, which has become a necessity, will shortly be opened The Ladies' Association is contributing £500 towards its cost and other donations have been received, but a further sum of about £500 is needed The committee is taking active steps for an extension of the hospital to cope with the increasing number of patients In the first six months of the year nearly 1000 were admitted.

DONATIONS AND BEQUESTS—The late Alderman John Bowen, J P, of Birmingham and of Malvern, left by will £1250 to the Birmingham General Hospital to endow a bed in memory of his son—By the will of the late Mr George Sparks, of Littlehampton, Sussex, the testator left £500 to the Littlehampton and District Hospital and £500 to the Littlehampton and District Nursing Association

ORDER OF THE NILE—The King has given his licence and authority to Dr O F H Atkey, Director of the Sudan Medical Service, to wear the insignia of the Third Class of the Order of the Nile, and to Dr R M. Humphreys, Inspector Sudan Medical Service, to wear the insignia of the Fourth Class of the same Order These decorations have been conferred by the King of Egypt in recognition of valuable services rendered by the recipients

KIDDERMINSTER HOSPITAL—Last week the Duke of York opened extensions to this hospital, to the cost of which the Prime Minister has contributed £5000 The extensions include two children's wards, one named after Princess Elizabeth, the Duke's baby daughter, and the other after Mr Stanley Baldwin They contain 40 beds, and the other improvements include an out-patient department and new scientific and medical equipment

METROPOLITAN ASYLUMS BOARD NEW APPOINTMENTS—At the meeting of the Board on July 24th Dr F H Thomson, medical superintendent, North-Eastern Hospital, was appointed chief medical officer, Infectious Hospitals Service, in succession to Dr F Foord Caiger At the same meeting the Board also appointed Dr. Eliot Swainston and Dr Alexander Joe as medical superintendents in their Infectious Hospitals Service Dr Swainston, who has been senior assistant medical officer in the Board's Infectious Hospitals Service since 1909, has been allocated to the South-Western Hospital, and will take up duty there on Oct 5th Dr Joe, who is at present assistant medical officer of health, city of Edinburgh, has been allocated to the North-Western Hospital, and will fill the vacancy which will shortly be caused by the retirement of Dr E W Goodall

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION—Arrangements have been made at the Brompton Hospital to permit graduates to attend the daily clinical practice of the hospital during August The small fee charged is payable to the secretary of the Fellowship, who will issue the necessary permit The Queen's Hospital for Children, Bethnal Green, will give an all day course from August 16th to 28th, in which the diseases of children of all ages will be dealt with from both a medical and surgical standpoint The hospital staff have kindly undertaken to provide a simple lunch and tea, and graduates will have access to all parts of the hospital during the whole of the period From August 23rd to Sept 4th the Queen Mary's Hospital, Stratford, has organised an all-day brush up course for those who wish to renew their acquaintance with up-to-date hospital practice The time table provided includes demonstrations in general surgery, medicine, orthopædics, laryngology, &c. The hospital has a new pathological department and also maternity wards and antenatal clinics The City of London Maternity Hospital provides courses on obstetrics and child welfare, these are held weekly and are limited to four graduates Personal application must be made to the secretary of the Fellowship Practical courses in anæsthetics can be arranged at any time Full particulars of these and other courses, and copies of the *Post Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1

COLLEGE OF NURSING—The Queen has consented to become patroness of the College of Nursing Established in 1916, the College has a membership of over 25,000 Its headquarters in Henrietta-street, Cavendish-square, London, were officially opened by Her Majesty in May

Messrs Burroughs Wellcome and Co announce that they can now supply sodium salts of *d*-tartaric, *l*-tartaric, *meso*-tartaric, citric, fumaric, and mucic acids These agents are employed in the differentiation of bacterial types in which sugar reactions are untrustworthy or fail altogether

VIROL RESEARCH SCHOLARSHIP IN PATHOLOGY—The scholarship of £200 offered annually by the directors of Virol, Ltd, for the encouragement of research in clinical pathology, has been awarded by the examiners (Sir William Willcox, Sir Bernard Spilsbury, and Dr Knyvett Gordon) to Miss Thirza Redman, M B Liverp, M Sc, Ph D Lond., for research work on rickets

NORTH WALES MENTAL HOSPITAL OVERCROWDED Dr R W Branthwaite, the Commissioner of the Board of Control, who recently inspected this hospital at Denbigh, reported that it was overcrowded to the extent of 57 patients, "a position, having regard to the steady admission rate, that is disquieting" He strongly urged the provision of a properly equipped pathological laboratory, and the Committee of Visitors has now voted the necessary money.

MENTAL DEFECTIVES IN THE WEST RIDING—The West Riding County Council has decided to purchase Oulton Hall and 315 acres between Leeds and Pontefract, as the nucleus of a home for mental defectives in place of Rawcliffe Hall, near Goole, which the Board of Control considers to be very unsatisfactory The cost of acquiring Oulton Hall, which has until recently been a military pensions hospital, will be £22,500, and a further £30,000 will have to be spent upon making the place ready for 150 patients The Board of Control desires the county council to provide a home for between 1500 and 2000 patients, the cost of which would be not less than half a million; at present there are 1200 mental defectives in the West Riding A colony will have to be created upon the estate, and Oulton Hall would then be used as staff headquarters

THE POST-GRADUATE HOSTEL.—The Post-Graduate Hostel was inaugurated on Monday, July 26th, with an address from Sir D'Arcy Power, in which he, as President of the movement, hoped for its ample support not only from the post graduates themselves, but also from all members of the medical profession "The idea," he said, "is intended to meet the wants of those who are so young in spirit as to feel that there is still much to be learnt, and have left their practices for a time to see what advances medicine has made, or who are still so young in body as wisely to have determined upon a wanderjahr before settling to their life's work." He went on to describe the organisation of the hostel, the arrangements made at the Imperial Hotel for the accommodation of post-graduate students, and the plans arrived at for conducting discussions to be opened by prominent chairmen, while he alluded to the possibility of impromptu dances finding a place among the activities of the adherents

EPSOM COLLEGE—Founders' Day was celebrated at Epsom on Saturday last, July 24th, when Earl Grey of Fallodon presented the prizes and opened the new chemical block. The headmaster, Mr A. C Powell, was able to point to the erection of these new buildings as a proof of the progress of the school, since teaching accommodation for at least 100 more boys would be provided, while the raising of the admission age would merge the preparatory school into the general body Lord Grey gave an interesting address to a large assembly in which, while doing justice to the medical profession as a career which appealed alike to the imagination and the intellect, he demurred at too early a specialisation in education. Accordingly he approved the aim at Epsom to give the boy a good general training, while he expressed himself in favour of the maintenance of Greek as a school subject, and recommended to boys the study of natural history as a recreation

The new chemical block, which was designed by Messrs Barry and Son and built by Messrs Cropley Bros, comprises laboratories, a theatre, lecture-rooms and class-rooms, and the usual annexes for carrying out practical chemical work. The guests who inspected these were also able to see the transformation of the library, the large structural changes recently undertaken in the lower school building, and the new and beautiful panelling in the memorial chapel—these being the innovations which in the main account for a heavy expenditure during the year, and for the necessity of relaxing no pains to increase the income of the Foundation

Medical News.

UNIVERSITY OF OXFORD —At a Congregation held on July 24th the degree of Bachelor of Medicine was conferred on D I Rees, T C Hunt, J H Kennedy, and J N C Ford The Theodore Williams Scholarship in Physiology has been awarded to Frank Raymond Crookes (University College) and John H Hunt (Balliol).

UNIVERSITY OF LONDON —A meeting of the Senate was held on July 21st, the Vice-Chancellor, Sir William Beveridge, being in the chair —The thanks of the Senate were accorded to Mr Donald MacAlister for his offer to inaugurate a fund for the establishment of a medal in memory of his father, Sir John MacAlister, to be awarded to students at the School of Librarianship at University College; and regulations were adopted for the award thereof —Dr E B Verney was appointed as from August 1st, 1926, to the University Chair of Pharmacology tenable at University College He was educated at Tonbridge School, Downing College, Cambridge (1913–16), where he obtained a First Class in Part I of the Natural Science Tripos in 1916, and at St Bartholomew's Hospital (1916–18) From 1918–19 he served with the R A M C From 1921 to 1924 he was assistant in the Department of Physiology at University College, and since 1924 has been assistant in the Medical Unit at University College Hospital In July, 1922, he was awarded a Beit Memorial Fellowship and was re-elected for a fourth year in 1925 He has published a paper in the Proc Roy Soc (1926) and six papers in collaboration with others in the *Journal of Physiology* (1922–26), Proc Roy Soc (1925), &c —The resignations of Dr W E Curtis from the University Readership in Physics at King's College, on appointment to the Chair of Physics at Armstrong College, Newcastle-on-Tyne, University of Durham, and Dr Major Greenwood from the University Readership in Medical Statistics at University College, were accepted as from Dec 31st and July 31st, 1926, respectively —A Diploma in Nursing was instituted, and regulations were adopted for the award thereof —Among the doctorates conferred were the following D Sc in Biochemistry, Mr J H Quastel, an internal student of the Imperial College—Royal College of Science, for a thesis entitled "(1) The Relationship of the Chemistry of Resting Bacteria Towards Bacterial Growth, and (2) A Theory of the Mechanism of Oxidations and Reductions in vivo"—The Rogers Prize of £100 for 1926 was awarded to Dr Robert Coope for an essay entitled the Value of the Various Methods of Investigating Diseases of the Pancreas —The University Studentship in Physiology for 1926–27, of the value of £50 and tenable for one year in a physiological laboratory of the University or of a school of the University, has been awarded to Dr E T Conybeare He proposes to undertake research in physiology at Guy's Hospital, particularly on the clinical side, and possibly also to extend his work on anæsthesia in relation to its clinical application.—Dr E Graham Little has been elected chairman of the Council for External Students, Sir Holburt Waring chairman of the Finance Committee, and Sir Wilmot Herringham chairman of the Library Committee and of the Committee of the Medical Members of the Senate

At recent examinations the following candidates were successful —

M D EXAMINATION

Branch I, Medicine —Frank M Barnes, St Thomas's Hosp, Frank B Byrom, London Hosp, Mahmoud A B Demerdash, Univ Coll Hosp, Helen W Duncan, University of Liverpool, Louis Forman, Guy's Hosp, John T Ingram, London Hosp, Leslie M Jennings, St Bart's Hosp, and Eileen M Saxton, London Sch of Med for Women

Branch II, Pathology —Edward C Dodds, Middlesex Hosp

Branch III, Psychological Medicine —Isabella McD Robertson, St George's Hosp and Maudsley Hosp

Branch IV, Midwifery and Diseases of Women —Mary N Andrews and Barbara V Lucas, London Sch of Med for Women, Dulcie H Lukis, London Sch of Med for Women and St Mary's Hosp, Douglas A. Mitchell, Guy's Hosp, and Mildred M E Yate London Sch of Med for Women

Branch VI, Tropical Medicine —John A W Ebden, Westminster Hosp, and Richard M Morris (University medal), London Hosp and London School of Tropical Medicine

M S EXAMINATION

Branch I, Surgery —Arthur J Gardham, Univ Coll Hosp, Archibald L P Jeffery, St Thomas's Hosp, and Basil L Laver, Guy's Hosp

University College —The following awards have been made in the Faculty of Medical Sciences —Bucknill Scholarship Flora Hargreaves Epsom Scholarship C W F Burnett, Medical Entrance Exhibitions J C S Wells, M P Ellis Anatomy Gold Medal (Senior Class), D F Ogborn (since deceased), Silver Medal (Junior Class), Flora Hargreaves Histology and Embryology Silver Medal, Flora Hargreaves Organic and Applied Chemistry Silver Medal, P D Mottet Physiology Schafer Prize, A S Parkes, Gold Medal (Senior Class), Margaret D Wright Pharmacology Silver Medal, D F Ogborn (since deceased)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE —The following results are announced in the sessional examination (March to July) of the division of Tropical Medicine and Hygiene —

Passed with distinction R Crawford (winner of Duncan and Lalcaca medals), E G Sayers, J C Paisley, I G MacGregor, W Thomson, R W Thomas, T C Wakefield, R B Jackson, K A MacKay, J A. W Ebden, A F Babonau, and E Le Clezio

Passed D S Adkins, E M Clow, B G Wheatley, H M O Lester, A Schourenkoff, P Milne, C L. Digby Roberts, B E Ebden, W. S Urquhart, M K Murray, V A. Stookes, C C Taffs, I Magdi, I T Kunaratnam, G Sanders G C Bergman, A J Boase, J McNabb, V J G MacGregor, W Yuen, M D Macqueen, W D Pollard, D I Gracey, H J F Wood, J E Chow, M Din, A J Lee, G W Mearns, J E Howard, J H McDonald, A M K O'Halloran D D N Selvadurai, A Brooks, J Symington, B Merrin, C Kearney, N G Rodriguez, and B Chiostri

UNIVERSITY OF EDINBURGH —At the graduation ceremony held on July 23rd the following degrees were conferred —

DOCTOR OF MEDICINE

*William J Adie (in absentia), Stanley E Bethell, ‡Duncan G Cooper, Francis R Cripps (in absentia), ‡James P Davie, ‡James K D Ingram, Schalk W Joubert, †Ian E M'Cracken, James M Manson, *George A Masson, Johannes A Pienaar (in absentia), Ruth J D Ritchie, William A. Robertson, Robert C Scott, Jocelyn Mary S Scovell, and ‡Harry C Sinderson (in absentia)

* Awarded gold medal for thesis † Highly commended for thesis ‡ Commended for thesis

The degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on 145 successful candidates, whose names were given in THE LANCET of July 24th, p 207

The following awards have been made —Cameron Prize in Practical Therapeutics Henry H Dale, F R S, Head of the Department of Biochemistry and Pharmacology under the Medical Research Council Gunning Victoria Jubilee Prize in Chemistry George H Percival Gunning Victoria Jubilee Prize in Materia Medica George A. Masson Milner Fothergill Medal in Therapeutics Andrew Rae Gilchrist Lauder Brunton Prize in Pharmacology and Therapeutics Adam C White Ettles Scholarship and Leslie Gold Medal George Brown Allan Fellowship in Clinical Medicine and Clinical Surgery Derrick M Dunlop Stark Scholarship in Clinical Medicine John G Kininmonth M'Cosh Graduates and Medical Bursaries John B Colquhoun Mouat Scholarship in the Practice of Physic George Brown Buchanan Scholarship in Gynæcology Robert L Turner James Scott Scholarship in Midwifery May Jones Beaney Prize in Anatomy and Surgery James Ernest Monro Conan Doyle Prize Stanley Jackson Annandale Gold Medal in Clinical Surgery James E Monro Murdoch Brown Silver Medal in Clinical Medicine George R Burnett Scottish Association for Medical Education of Women Prize May Jones Dorothy Gilfillan Memorial Prize May Jones Sir Robert Jones Prize in Orthopædic Surgery James D A Gray Pattison Prize in Clinical Surgery James D A Gray Wightman Prize in Clinical Medicine Wilhelmina Mary Grace MacLennan Wellcome Medals and Prizes in the History of Medicine Gold Medal, Alexander F K Clarkson, Silver Medal, Duncan W D MacLaren Cunningham Memorial Medal and Prize in Anatomy Ernest L Godfrey Whiteside Bruce Bursary Arnold G M'Lean

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH —At a quarterly meeting of the College held on July 20th, the President, Dr G M Robertson, in the chair, Dr James Davie Gilruth was introduced and took his seat as a Fellow It was announced that Dr James Walker Dawson had been appointed Morison Lecturer for 1927 The Victoria Jubilee Cullen Prize was awarded equally between Dr G Lovell Gulland and Dr Alexander Goodall

ROYAL COLLEGE OF SURGEONS OF EDINBURGH —At a meeting of the College held on July 23rd, Dr A Logan Turner, the President, in the chair, the following 28 successful candidates out of 66 entered, who passed the requisite examinations between March 29th and April 5th, were admitted Fellows —

Robert F Aitken, Harnandlall Batra, Charles E M Blumer, Richard R S Bowker, William H B Bull, Alexander W Davidson, George V Davies, Homi Darashaw Gandhi, William C Gray, Charles W Harrison, Neil R Houston David R Jennings, Oswald E J McOustra, Hugh Miller, John C Moir, Phani Bhusam Mukerji, Thomas Nicol, James R K Paterson, Roland L Raymond John J Robb, Gerald I Secluna, Arthur B Smith, John Sturrock, James E Sykes, Elizabeth N Thompson, Esmond F West, Robert K. Wilson, and William A -Dains Woolgar

Notes, Comments, and Abstracts.

BRITISH CHEMICAL PLANT EXHIBITION

THIS exhibition, organised by the British Chemical Plant Manufacturers' Association in connexion with the forty-fifth annual meeting and congress of chemists was held at the Central Hall, Westminster, from July 19th to 23rd, and enabled visitors to gain some idea of the development and excellence of chemical plant produced in this country The exhibition, opened by Sir Max Muspratt, and designed primarily for the benefit of chemical engineers and users of chemicals, contained many exhibits of interest to the lay mind, which, if not of immediate medical application, were of importance in the preparation of pharmaceutical and biochemical therapeutic substances

A general survey of the numerous apparatus showed the attention devoted to the production of non-corrodible alloys, three firms—namely, Messrs Hadfields Ltd Firth and Sons, and Brown-Bayley—showing samples of, and tests upon, stainless steels adapted for various uses, whilst Messrs Houghton's and the Lennox Foundry Co provided different types of plant constructed of the well-known corrosion-resisting cast-iron alloys, "ironac" and "tantiron" To appreciate the value of the introduction of these alloys it is necessary to realise the many corrosion-inducing conditions under which they are used in chemical industry Among other metals represented, and applied either alloyed or in the pure state, to the construction of plant, &c, may be noticed copper, nickel, aluminium, and tin, the nickel laboratory apparatus of the Mond Nickel Co having a well-deserved reputation A striking exhibit by the Thermal Syndicate well illustrated the many utilitarian applications of their translucent or transparent silica product, "vitreosil," and among the samples exhibited were noticed small syringes, the sterilisation of which could be carried out with facility and without risk of fracture

The display of apparatus by Messrs Negretti and Zambra showed no striking novelties, but a wide range of thermometers, hydrometers, and continuous distance recording instruments such as pyrometers, depth gauges &c, whilst an interesting brochure entitled 'The History of the Thermometer" was distributed gratis by the firm's representative Bacteriological sterilisers of various types were shown by four firms, one of which, Messrs Brown Bros also exhibited their well-known and highly-efficient patent stills for the preparation of distilled water, in addition to numerous forms of laboratory gas and water taps The Webb colloid mill provided by Messrs Baker Perkins is a device in which a new principle is adopted for the preparation of emulsions, and Messrs Bennett, Sons and Shears drew attention to their patent "mulser" for rendering emulsions permanent by forcing them under pressure against a revolving disc From this machine the average output is 20 gallons per hour.

The Kestner Evaporator Co, Ltd, showed a very compact water-softening plant, in which one of the newer and high-efficiency permutitic compounds is employed This apparatus completely softens about 700 gallons of an average hard water, and requires only 7 lb of common salt for complete regeneration Attention was also directed to a form of horizontal evaporator, constructed chiefly of copper and widely used at the present time for the concentration of fruit juices solutions of insulin, and other liquids The exhibit of the Cape Asbestos Co served to illustrate the wide applicability of the different forms of asbestos, and, considering the readiness with which this substance may be sterilised, it is somewhat difficult to understand why it finds little or no use in surgery

Many examples of plant used for large-scale chemical manufacture were also on exhibition, and there was ample evidence of the skill and ingenuity of the British chemical engineer

THE PREVENTION OF POISON ACCIDENTS

UNDER the name of the "Porcupine" poison-bottle stopper, the Waverly Comb Co, Ltd, 374-8, Old-street, London, E C, have placed on the market bottle corks of varying sizes which have a wooden metal covered head from the periphery of which project small blunt spikes so that in withdrawing the cork from the bottle care has to be taken that the fingers do not come into contact with them If the cork is grasped carelessly, or in the dark, the sense of touch at once makes the person aware of the unusual nature of the stopper, and thus attention is called to the bottle Many accidents have occurred through mistaking a poison bottle for one containing other substances, and the invention ought to go a long way towards reducing the number of accidents which occur from this cause It is, however doubtful whether any invention can be a substitute for common sense and care, the human factor must always be reckoned with

A SKIN REACTION FOR TYPHOID

IN an article reprinted from the *Semana Medica* (No 19, 1926), Dr G Rodriguez, of Buenos Aires, gives a further account of his skin reaction for typhoid [1] In this article he states that his reaction is intended as a test of individual susceptibility His object is to discover why apparently two-thirds of the population are not susceptible to typhoid and he hopes to evolve a means of finding out those individuals who ought to be inoculated against the disease

He finds 8,000,000 organisms from Vincent's vaccine to be the most satisfactory dose but gives tables showing the effects of double and quadruple doses The most interesting table is that showing the results in persons who had been vaccinated against typhoid at different periods The reaction in the great majority of those who had been recently vaccinated (i e, about two months previously) was negative, but in those vaccinated over a year it was strongly positive This he explains as meaning that the organism is in an allergic state, it is hypersensitive to the typhoid protein (bacilli), but still protected against actual infection Dr Rodriguez still considers that his previous experiments, with only 2,000,000 bacilli, provide a test which is of some value for diagnosis if positive in the early stage of typhoid and for prognosis if negative in the later stage, but he admits that further experience is necessary

AN ALMONER'S DEPARTMENT

THE annual report of the almoner's department at St Thomas's Hospital, a substantial pamphlet of nearly 80 pages is full of interest. The department's activities are varied and laborious and the psychological side of them often deeply interesting A constantly recurring difficulty is the ignorance and apathy of the majority of hospital patients about their rights as insured persons, and their reluctance, at first sight, to realise that insurance and the keeping up of payments concern them and their future lives "A great many cases are sent to the almoner in the out-patient department for purely social reasons, maladjusted family life, difficult adolescence, and troubles arising from jealousy, fear remorse, or loneliness" Patience and sympathy are usually successful in removing these difficulties Bad housing gives the almoner abundant trouble "It is not easy to move families nor is it always possible to know what constitutes technical overcrowding" For example, a child of 18 months, suffering from conjunctivitis and probable keratitis since birth belongs to a family several members of which have attended the eye department on and off for years 'Three girls of 19, 14, and 13, the father, and a boy of 12 all slept in one room, the mother and three younger children in the kitchen." The local M O H, it is stated, did not consider this a case of overcrowding In circumstances such as these it is impossible to deal effectively with obstinate eye troubles There is an increase in the number of patients who have to be "discharged as well able to pay for any form of treatment" One of the heaviest pecuniary charges is the cost of transporting patients to and from the hospital for treatment which, although it is provided only when absolutely necessary, last year cost £729 The lady almoner is Miss A E Cummins

ANNUAL CHARITIES REGISTER

THE Annual Charities Register and Digest is a classified register of charities in or available for London The number of these deriving their income from purely metropolitan sources and expending it solely upon metropolitan cases is comparatively small; but the number which, while located in the metropolis, derive their income from all parts of the Kingdom, or afford assistance to applicants from all parts, is very large Excluding missionary and spiritual institutions the turnover of the institutions enumerated in the Charities Register from which information could be obtained amounted in 1923 to rather more than £15,000,000 Voluntary contributions accounted for about £6,700,000 and £1 150,000 came from legacies From these figures alone it is evident that London charities are of immense importance in the national life but even more remarkable are the number and variety of the organisations at work for the relief of suffering The Register and Digest,[2] issued for the Charity Organisation Society by Longmans Green and Co has reached its thirty-fourth edition and is a clear and concise reference book now well-known for its useful and comprehensive information To compile and publish works of this kind is a laborious task, and Londoners are fortunate in having at their disposal so good a guide to the charitable societies and institutions of the area.

THE death is announced of Mr Henry Kemp-Welch, for over 23 years secretary of Cheyne Hospital for Children, Chelsea Mr Kemp-Welch, who retired last year, had been connected with the hospital practically since its foundation 51 years ago

PRESENTATION TO SIR JAMES CRICHTON-BROWNE —Sir James Crichton-Browne has resigned the office of treasurer of the Royal Institution, which he has held for 37 years, and as a memento of his valuable work his fellow members have given him a silver cup The presentation was made on July 20th by the Duke of Northumberland, who said that it was a striking testimony to Sir James Crichton-Browne's services that during his term of office the endowment fund had risen from £22,713 to £122,500 The work itself had been done in the intervals of a busy life whose motive was always a love of and zeal for the truth, and in their friend they had a rare combination of devotion, sound judgment, unfailing tact, and the ability to inspire confidence and friendship Sir James Crichton-Browne, in acknowledging the gift, predicted increasing success for the work of the Institution

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, Wimpole street, W

MONDAY, August 2nd, to SATURDAY, August 7th —WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W Special Course, consisting of clinical demonstrations upon selected cases, will be given at this Hospital at 5 P M as follows —Tues, Dr Hobhouse Disseminated Sclerosis Wed, Dr Hobhouse Hemiplegia and Local Cerebral Lesions Thurs, Dr Macnamara The Sequelæ of Encephalitis Lethargica Frid, Dr Worster Drought Clinical Forms of Neuro-Syphilis

Appointments.

CLAPHAM, H, M R C S, L R C P Lond, has been appointed one of the Medical Referees under the Workmen's Compensation Act for the Districts of the County Courts of *Biggleswade, Huntingdon, Peterborough,* St Neots, and Thrapston and Oundle

HOWELL, B WHITCHURCH, F R C S Eng, *Honorary* Surgeon to Cheyne Hospital for Children, Chelsea

SOUTER, W C, M B, Ch B Aberd, Ophthalmic Surgeon to the Aberdeen Royal Infirmary

SWAINSTON, E, M D, B S Durh, D P H *Camb*, Medical Superintendent of the South-Western Hospital, Stockwell, S W, Metropolitan Asylums Board

Metropolitan Asylums Board JOE, A, M D, Ch B, D P H Edin, and SWAINSTON, E, M D, B S Durh, Medical Superintendents

Willesden General Hospital BOURNE, A W, M B Camb, F R C S Eng, a Member of the Honorary Consulting Staff, PHILLIPS, L G, M S, M B Lond F R C S Eng, *Honorary* Gynæcologist

Certifying Surgeons under the Factory and Workshop Acts CURRIE, S H, L R C P Lond, M R C S (Swanscombe), MITCHELL, J C D, M B, Ch B Glasg (Berwick), RAMAGE, J H, M B, Ch B Glasg (Neilston, Renfrew)

Sheffield Royal Hospital —Surg Reg
Western Australia —Inspector General of the Insane £960

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Bollington (Cheshire)

Births, Marriages, and Deaths.

BIRTHS

HAYDEN —On July 18th, at Graham road, Hendon, the wife of Captain A F Hayden, M B, F R C S, I M S (retd.), of a daughter

MACKAY —On July 17th, at Cliftonville, the wife of Dr J M Mackay, W A M S, of a daughter

PENDERED —On July 25th, the wife of J H Pendered, M.D, F R C S, Cumberland House, Southampton, of a daughter

MARRIAGES

LIVINGSTON—EDWARDS —On July 21st, at Wonston, Hants, Alexander Livingston, M B, Ch B, M D S, to Margaret Aubrey, third daughter of Canon W G Edwards, M A., and Mrs Edwards, of Wonston Rectory

DEATHS

MACLAGAN —On July 19th, at Ravensdowne Berwick upon Tweed, Charles George Maclagan, M B, C M, aged 66

PERRY —On July 18th, accidentally drowned, Lionel Banks Perry, *M B, B C Camb*, aged 41

SEYMOUR —On July 24th, at Debourne, Cowes, I W, Edgar William Seymour, M V O, M B Camb

THOMSON —On July 18th, at Bridge street, Musselburgh, Midlothian Andrew Douglas Ramsay Thomson, F R.C.P. Edin, aged 74

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages and Deaths

FUNCTION AND DESIGN.

Delivered before the Section of Physiology of the British Association at Oxford on August 5th, 1926,

By J B LEATHES, M B Oxf, F R C S Eng, F R C P Lond, F.R S,

PRESIDENT OF THE SECTION, PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF SHEFFIELD.

Among natural sciences physiology takes a place which in one respect is different from that taken by any other It studies the phenomena of life, but more particularly the ways in which these phenomena are related to the maintenance of life Anatomy and morphology are concerned with the forms of living organisms and their structure, biological chemistry, as distinct from physiology with the composition of the material in which the phenomena of life are exhibited The province of physiology, in studying the functions of these forms and of this material, is to ascertain the contributions that they make to the organisation of the living mechanism, and learn how they minister to the maintenance of its life Function implies ministration, structure for physiology implies adaptation to function, what in a word may be termed design

The Fundamental Attributes of Life

Ultimate analysis of the phenomena with which physiology deals leads to the fundamental distinction between matter in which life is manifested and matter in which it is not. Life is exhibited only in aqueous systems, containing unstable, perishable combinations of carbon with hydrogen, nitrogen, sulphur, phosphorus, and oxygen, in the presence of certain inorganic ions, those which are present in the sea, the native environment originally of all forms of life, and the inalienable property that such matter exhibits when alive, and that matter which is not alive does not, is that these unstable organic combinations are for ever reforming themselves out of simpler combinations that do not exhibit this property and do so at a rate which averages at least not less than that at which they break down This power of self-reformation, spontaneous regeneration, operates not only when living organisms, cells or communities of cells are growing or reproducing their kind, the very maintenance of living existence requires by definition that it should persist In the absence of water the living process may sometimes apparently be suspended for a time as it may be if the surrounding watery medium is immobilised by cold it is a question whether this is anything more than a retardation to a rate of change that is imperceptible by the ordinary methods of observation, and a question how long such suspended animation is possible where it is possible at all It is only where water has the kinetic activity of the liquid state that spontaneous regeneration of living matter can in general proceed and then it must, for when it ceases the unstable material ceases to live

Chemical analogies for this power of spontaneous regeneration if such exist can only exist in part, in the present state of our comprehension of it, certainly, it is hazardous to try to trace them The attempt so commonly made to trace one between the growth of living matter and the growth of crystals in a saturated solution it is safe to say is in so many respects on the wrong lines that it is merely misleading Crystals are not alive The molecules that constitute the crystal are set in solid formation, so long as the crystal exists they are stable and unchangeable These molecules collect on the growing crystal but they exist ready-made in the surrounding solution they do not come into being by the influence of the crystal; they are themselves so constituted as to take up a set position in relation to each other and to those already ranged side by side in the crystal, as soldiers on the drilling-ground at the word "fall in"; they are available because the solution is kept saturated by the dissolving of smaller but similar crystals that for physical reasons are more soluble in the solution than the larger ones In contradistinction to this, the molecules that enter into the composition of living matter exhibit the phenomena of life only when permeated with water molecules exercising the kinetic activity of the liquid state; they are unstable and perishable; the added molecules, some of which even during growth and all of them at other times, serve but to replace those that perish, do not exist ready-made, they come into being only in conformity to the pattern and under the influence of those already in existence, a pattern that these alone can use, and they are formed out of material that is chemically different from them

The Implications of Spontaneous Degeneration

Let us for a moment consider what this spontaneous regeneration implies Of the various chemical components of protoplasm proteins are generally considered the most important, often the only important, ones The elucidation of the chemical principles upon which the structure of proteins rests, which took place about the beginning of this century, was, like the neurone hypothesis of the structure of the nervous system, an advance the magnitude of which only those perhaps can appreciate who began the study of physiology well back in an earlier one For a time it seemed in each case that the problem was solved and all that was to follow was simple Those were great days The best-known varieties of proteins, when detached and uprooted from the place where they grew, consist of chains of about a hundred, sometimes nearly two hundred, links Each link is an amino-acid coupled by its acid group to the amino group of one neighbour and by its amino group to the acid group of its other neighbour, a molecule of water being lost at each linkage There are not more than about twenty different amino-acids, so that some of them must occur several times in the chain; in some kinds of protein one amino-acid may occupy 30 or 40 of the 100 places in the chain In any such isolated protein it is probable that the order as well as the proportion in which each amino-acid occurs in the molecule is fixed, and it is this specific order and proportion that accounts for the specific character and properties of the protein What could be simpler? And only yesterday all was so obscure

It is not recorded that in the rush of this advance anyone stopped to reflect what number of formations such a protein might still possibly have Supposing it were a chain of only 50 links a very simple case · if all the links were different the number of possible permutations is denoted by the innocent-looking symbol $\lfloor\underline{50}$ If, instead of all being different one kind of link recurred ten times, the number would be reduced to $\lfloor\underline{50} / \lfloor\underline{10}$ If, in addition, there were four that recurred four times and ten that recurred twice, it would be further reduced to

$$\lfloor\underline{50} / \lfloor\underline{10} \times (\lfloor\underline{4})^4 \times (\lfloor\underline{2})^{10}$$

It would now consist of a chain of only 50 links of which there were only 19 different kinds, and the number of different arrangements of its parts would be about 10^{48} Astronomy deals with big figures Light it is said takes 300 000 years to travel from one end of the Milky Way to the other, this distance expressed in Angstrom units 10 000 000 of which go to a millimetre, would be less than 10^{32} So far are we from knowing the structure of protein molecules So far are we from knowing what variations in disposition of the parts in such a molecule may not occur without our being within a measurable distance of detecting them For if the number of possible varieties of a protein whose molecular weight is known and known to be exceptionally small and

CHEMISTRY, PURE AND APPLIED

To peruse the pages of a classified price-list on Exact and Applied Science, Part VII, such as that recently issued by Messrs H Sotheran and Co, containing the titles of nearly *4000 volumes devoted to chemistry and chemical technology*, is a liberal education in the history of these sciences The items included in the present list range throughout the various phases in the development of chemistry from the earliest speculative theorising through the period of alchemical investigations, with its gradual evolution into the age of accurate experiment, observation, and deduction, to the present time To the readers of THE LANCET the fact that so many of the authors of works on pure and applied chemistry from the seventeenth to the early nineteenth centuries were medical men will not be without interest ministers of religion are, however, in serious competition The brief annotations, appended to many of the items, being erudite without dullness, and frequently humorous, prevent the ennui that might be expected from the reading of a catalogue

A rapid survey of the various entries enables us to realise the wealth of material available. Thus a complete set of the Transactions of the Royal Society of Arts, dating from 1783 to 1845, in good condition, a highly important and rare series, is quoted at a very moderate figure Numerous works of that versatile author, F C Accum, famous for his exposure of food adulteration under the subtitle of "Death in the Pot," are offered, including his manuals on chemical instruction, brewing, wine making, and the manufacture and use of coal-gas Among other rare works are to be found Schmidlap's German treatise on fireworks dated 1564, the "Art of Photogenic Drawing" by Fox Talbot, Kunckel's "Ars Vitraria Experimentalis," and Stephen Hale's "Statical Essays," a description of early experiments in plant and animal physiology The catalogue is admirably arranged and will prove of interest to senior and research students, analysts, the connoisseur of rare works and all interested in the history and controversies of chemical science, each of whom will find within its covers much that will appeal to his taste

A BURIAL IN THE MARKET-PLACE

PUBLIC health administration is perhaps humdrum in this country Not so, however, in Calcutta The *Indian Medical Record* (May, 1926) protests against the turning of a public market in that city into a burial ground The facts as given in the *Record* were, briefly, as follows A beggar died in the market, and after his death some of the butchers suddenly took it into their heads that the man was a saint They insisted on burying the body in the very place where he had died In such a case the proper procedure would have been to inform the police, who would have disposed of the body This was not done—rather, in the very presence of the deputy mayor of Calcutta, the body was buried inside the market near to the place where foodstuffs were sold Later the corporation appointed a special market committee to thresh out the matter They did this thoroughly, for they obtained evidence that (1) the deceased fakir was a Christian, (2) had been convicted in a stabbing case and sentenced to imprisonment, (3) the sentence had been remitted on the occasion of the Queen's Diamond Jubilee, (4) no express, valid, or implied permission had been given for the burial—on the contrary "the attitude of the authorities was directly against the burial from the beginning to the end" [and attitude is static] In the opinion of the Advocate-General for Bengal the body had been unlawfully buried on the property of the corporation, who were not only entitled to exhume and remove the body, but were also not precluded by anything that had happened from doing so In August, 1925, the corporation definitely resolved that if within two months of the date of that meeting no one came forward to do it, the chief executive officer should exhume the body and bury it in a proper place Nothing had been done since that previous resolution It was clear to the *Indian Medical Record* that not only had the Calcutta Corporation made a laughing stock of themselves, but that their folly endangered the public health To us it is even clearer that the difficulties of public health work in India lie not mainly with the parasitic or climatic causes of disease

A CHILDREN'S SPA

THE mineral springs of Mont Dore have for many years been known to balneologists of all countries, and have an established reputation in the treatment of respiratory complaints Dr A Debidour and Dr K. Eckenstein[1] give an interesting account of an original and enterprising development which has taken place there in recent years, as the result of which the treatment of children has become one of the principal features of Mont Dore It is obvious that this object could not be achieved without some fairly extensive reorganisation of the routine, the customary programme of a spa would present little attraction to children, and their presence in large numbers would be incompatible with the comfort of many adult patients Accordingly a special children's department was equipped, in which separate inhalation chambers were provided for boys, girls, and small children, under the management of a nurse. Push-ball and other attractions are employed to popularise the visit to the inhalation room and to stimulate respiration The vapour baths are supplemented by a school of respiratory education in which the children are taught exercises which develop the respiratory muscles The exercises take place both in the open air and in a gymnasium, and are astutely combined with games of various kinds The Mont Dore treatment is indicated for children with enlarged tonsils and adenoids, both before and after operation, as well as for asthmatics, and encouraging results have been obtained in increasing the lung capacity and the general condition of the patients

UNIVERSITY COLLEGE HOSPITAL APPEAL

THE extension of the hospital's work, made possible by the Rockefeller Foundation's gift, has increased the number of beds available by 202 Although most of these are already endowed, it is estimated that the regular income will have to be increased by at least £15,000 a year if the establishment is to be properly maintained There is already a debt of £20,000, and in connexion with a special appeal for the maintenance fund an illustrated booklet entitled "A Meeting of the Ways" has been prepared which gives an account of the hospital's history and services to the community

SMOKING AND FIRE WORSHIP

To the Editor of THE LANCET

SIR,—In THE LANCET of May 22nd last the habit of smoking is treated from an American as well as from a British standpoint (Sir Humphry Rolleston's address and the notes of Dr J Rosslyn Earp, of Antioch College, Ohio) Both communications, in my opinion, are defective in so far as they do not give sufficient importance to inheritance, often a dominating factor The brain of to-day is a continuation of the brain of yesterday, in other words, we inherit what was transmitted or given us by our ancestors, and the difference in quality is but slightly discernible If we hark back hundreds of years expecting vast changes in brain development we are disappointed, even thousands of years can be looked upon as yesterday in the ladder of evolutionary ascent, so that the brain of to-day and the brain of yesterday react almost equally in similar circumstances Tobacco, the drug, acts as a liberating agent to nervous energy, like theine, caffeine, cocaine, matein, and similar narcotics in moderate doses, and facilitates nervous combustion, yet the mental attitude of the smoker depends but partially on nicotine, the narcotic, and chiefly on the act of smoking as an intricate rite

Let us picture before our mind's eye a smoker, and follow him step by step, we will be convinced that in his moments of exaltation he has entered the moods of his fire-worshipping ancestors There he is—the modern smoker—leaning back in an arm-chair with a pipe in his mouth casting fragments of interrupted sentences at you from between clenched teeth He now strikes a match, holds its lighted head above the bowl of the pipe, draws but finds the tobacco too loosely packed Inserting his left index finger into the mouth of the bowl he packs the tobacco tighter Meanwhile he holds fingers, fire, and bowl in such close proximity you would fain hurry the lighting to avoid burns, but no he hugs the approximation, lingering over the warmth, and dwells fondly on the flickering flame before it dies The tobacco alight, he peers into the glowing bowl and uplifting column of smoke, impelled upwards as if by subdued outburst of energy from the rotund receptacle His gaze may be deflected from the column to cones of vapour ejected at intervals from his mouth, or on an occasional wreath revolving its ascent skywards, intensifying his brood into that of semi-mesmerism

In his present mood he is subconsciously participating in the experience of his fire-worshipping ancestor who gloried in sacrifice and the transmutation of matter through that ghoulish column into what he considered was a spirit-world The smell of burning flesh, the crackling and simmering, the whole gamut of colours displayed in the offering, the death dance of the ascending column, created a religious fervour and exaltation attenuated somewhat in the offspring that smokes his pipe of tobacco An impoverished setting diminishes the exaltation Surely no present-day mind can disentangle itself from the past

I repeat, what the centuries have bequeathed reacts in more or less the same way in similar circumstance

I am, Sir, yours, faithfully,
M A I

Buenos Aires, June 30th, 1926

A CORRESPONDENT inquires in what dosage and at what intervals emetine should be used in hæmophilia

---

An Address
ON
FUNCTION AND DESIGN.

Delivered before the Section of Physiology of the British Association at Oxford on August 5th, 1926,

By J B LEATHES, M B Oxf, F.R C S Eng, F R C P Lond, F.R S,
PRESIDENT OF THE SECTION, PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF SHEFFIELD

Among natural sciences physiology takes a place which in one respect is different from that taken by any other It studies the phenomena of life, but more particularly the ways in which these phenomena are related to the maintenance of life Anatomy and morphology are concerned with the forms of living organisms and their structure; biological chemistry, as distinct from physiology, with the composition of the material in which the phenomena of life are exhibited The province of physiology, in studying the functions of these forms and of this material, is to ascertain the contributions that they make to the organisation of the living mechanism, and learn how they minister to the maintenance of its life Function implies ministration, structure for physiology implies adaptation to function, what in a word may be termed design

The Fundamental Attributes of Life

Ultimate analysis of the phenomena with which physiology deals leads to the fundamental distinction between matter in which life is manifested and matter in which it is not. Life is exhibited only in aqueous systems containing unstable, perishable combinations of carbon with hydrogen, nitrogen, sulphur, phosphorus, and oxygen, in the presence of certain inorganic ions, those which are present in the sea, the native environment originally of all forms of life; and the inalienable property that such matter exhibits when alive, and that matter which is not alive does not, is that these unstable organic combinations are for ever reforming themselves out of simpler combinations that do not exhibit this property and do so at a rate which averages at least not less than that at which they break down This power of self-reformation, spontaneous regeneration, operates not only when living organisms, cells or communities of cells are growing or reproducing their kind; the very maintenance of living existence requires by definition that it should persist In the absence of water the living process may sometimes apparently be suspended for a time, as it may be if the surrounding watery medium is immobilised by cold, it is a question whether this is anything more than a retardation to a rate of change that is imperceptible by the ordinary methods of observation, and a question how long such suspended animation is possible where it is possible at all. It is only where water has the kinetic activity of the liquid state that spontaneous regeneration of living matter can in general proceed, and then it must for when it ceases the unstable material ceases to live

Chemical analogies for this power of spontaneous regeneration if such exist can only exist in part, in the present state of our comprehension of it. certainly, it is hazardous to try to trace them The attempt so commonly made to trace one between the *growth of* living matter and the growth of crystals in a saturated solution, it is safe to say is in so many respects on the wrong lines that it is merely misleading Crystals are not alive The molecules that constitute the crystal are set in solid formation · so long as the crystal exists they are stable and unchangeable These molecules collect on the growing crystal but they exist ready-made in the surrounding solution they do not come into being by the influence of the crystal; they are themselves so constituted as to take up a set position in relation to each other and to those already ranged side by side in the crystal, as soldiers on the drilling-ground at the word "fall in"; they are available because the solution is kept saturated by the dissolving of smaller but similar crystals that for physical reasons are more soluble in the solution than the larger ones In contradistinction to this. the molecules that enter into the composition of living matter exhibit the phenomena of life only when permeated with water molecules exercising the kinetic activity of the liquid state they are unstable and perishable; the added molecules, some of which even during growth and all of them at other times, serve but to replace those that perish do not exist ready-made, they come into being only in conformity to the pattern and under the influence of those already in existence, a pattern that these alone can use, and they are formed out of material that is chemically different from them.

The Implications of Spontaneous Degeneration.

Let us for a moment consider what this spontaneous regeneration implies Of the various chemical components of protoplasm proteins are generally considered the most important, often the only important, ones The elucidation of the chemical principles upon which the structure of proteins rests, which took place about the beginning of this century, was, like the neurone hypothesis of the structure of the nervous system, an advance the magnitude of which only those perhaps can appreciate who began the study of physiology well back in an earlier one For a time it seemed in each case that the problem was solved and all that was to follow was simple Those were great days The best-known varieties of proteins when detached and uprooted from the place where they grew, consist of chains of about a hundred, sometimes nearly two hundred, links Each link is an amino-acid coupled by its acid group to the amino group of one neighbour and by its amino group to the acid group of its other neighbour. a molecule of water being lost at each linkage There are not more than about twenty different amino-acids, so that some of them must occur several times in the chain, in some kinds of protein one amino-acid may occupy 30 or 40 of the 100 places in the chain In any such isolated protein it is probable that the order as well as the proportion in which each amino-acid occurs in the molecule is fixed, and it is this specific order and proportion that accounts for the specific character and properties of the protein What could be simpler? And only yesterday all was so obscure

It is not recorded that in the rush of this advance anyone stopped to reflect what number of formations such a protein might still possibly have Supposing it were a chain of only 50 links a very simple case · if all the links were different the number of possible permutations is denoted by the innocent-looking symbol $\underline{|50}$ If, instead of all being different one kind of link recurred ten times, the number would be reduced to $\underline{|50} / \underline{|10}$ If. in addition, there were four that recurred four times and ten that recurred twice, it would be further reduced to

$$\underline{|50} / \underline{|10} \times (\underline{|4})^{4} \times (\underline{|2})^{10}$$

It would now consist of a chain of only 50 links of which there were only 19 different kinds, and the number of different arrangements of its parts would be *about 10^{48} Astronomy* deals with big figures Light it is said takes 300 000 years to travel from one end of the Milky Way to the other: this distance expressed in Angstrom units, 10 000 000 of which go to a millimetre would be less than 10^{32}. So far are we from knowing the structure of protein molecules So far are we from knowing what variations in disposition of the parts in such a molecule may not occur without our being within a measurable distance of detecting them For if the number of possible varieties of a protein whose molecular weight is known. and known to be exceptionally small, and which contains the several amino-acids in a known proportion, is as great as this, the number that is possible when that proportion may be changed is practically incalculable, each change in proportion being capable of a number of new arrangements that could be calculated, as was done for our hypothetical case

But in the living cell, where these chains are put together, each link must first be fashioned and then forged into the chain, unfinished chains *in statu nascendi* must exist which our analytical methods can never detect In such unfinished chains the order presumably in which the amino-acids are linked up is observed, but the proportion must be different from that in the finished product, for in a chain of nearly a hundred links a particular amino-acid—cystine, for instance—may occur only once

Analogy of Crystal Formation

Now it is possible that the analogy of crystal formation may be applied to the reproduction of the characteristic order in which the linkings occur, and that the parts out of which a new chain is to be formed may be collected and brought into position alongside of the corresponding parts of an existing chain by forces that are similar to those that determine the latticed relations of atoms in a crystal But something more than this is required to account for the linking up of these links by the loss of water, and still more for the fashioning of the links themselves. In plants all varieties of amino-acids come into being as required, in animals, it is true, some must be supplied ready-made in the medium in which the proteins grow; but even in animals some of them can be formed from material of a totally different nature

Wherever this is the case we have to suppose that it is by selective emphasis of certain otherwise unemphasised but possible arrangements of atoms or groups of atoms, evidence for the occurrence of which under similar conditions in the absence of life is generally not obtainable Specific catalysed syntheses must cooperate with the forces that merely sort out and place in proper order the assembled parts, and must fashion for them the particular links that they need at each step Specific catalytic agents playing an important part in cell chemistry are familiar in the enzymes found in digestive secretions and also locked away within the cells themselves There is much to support the idea that such agents act by modifying the chaotic, indeterminate, kinetic agitation of certain kinds of molecules in their immediate neighbourhood in such a way that the relative positions in space of groups capable of reacting with one another tend to become those in which reaction is likely to occur, and to occur in conformity with a certain pattern The peculiar thing about the chemistry of living matter is not that the reactions that are characteristic in it are novel, but that in the rough and tumble of ordinary liquid systems their occurrence is almost infinitely improbable Where there is life circumstances exist which make them the rule Anyone conversant with work in animal metabolism can supply many illustrations, for instance, it has been shown that in a simple solution of the amino-acid alanine traces of methyl glyoxal occur; in the animal body there is reason for thinking the reaction may become practically quantitative Forces which determine the relative positions of adjacent foreign molecules and so affect their behaviour are something to which there is no analogy in the growth of crystals in a saturated solution

Moreover, if the forces that determine the reproduction of a certain order in the arrangement of the parts of a protein are similar to those that determine the lattice pattern of a crystal, the crystals with which the comparison is made are solid, and life is manifested only in liquid aqueous systems The analogy should rather be with the formation of liquid crystals, a phenomenon that is itself as yet too unfamiliar to shed common light on the obscurity of spontaneous regeneration The ordered disposition of the ultimate components of protoplasmic systems is such as to leave play, generally but little checked, for the fluid properties of water, and in some modified degree, too, of molecules and ions dissolved in water Even a solid jelly may include within its protein framework a hundred times its weight of water in which diffusion is free to take place almost as if the framework were not there, and protoplasm, with commonly twenty times as much protein in it as this, more often resembles a fluid of varying viscosity than a solid gel, which means that the great protein chains float and drift in the whirlpool of kinetic agitation, observing, it may be, so far as is possible, certain unstable relations to their kind, but with no rigid fixity It is commonly felt that the behaviour of unicellular organisms makes the hypothesis necessary that there is an insoluble surface layer that keeps the watery contents of the cell from dispersing in the water that surrounds it Much experimentation, and no lack of speculation, has not made clear what the nature and structure of this limiting layer is It may be that the flexible cohesion at many alternative points between clinging floating chains of amino-acids, the innermost of which are made fast to the nucleus, may go some way to maintain the identity of the cell and prevent its contents from scattering

Chemical Meaning of Material Life

But in the chemical make-up of protoplasm, proteins, the most abundant component, are not the only ones that are necessary Pre-eminent among the others are the nucleic acids When we consider what has been learnt of the behaviour and of the chemical composition of the nuclear chromosomes, and that according to Steudel's reckoning the nucleic acids form 40 per cent of the solid components of these chromosomes, into which are packed from the beginning all that pre-ordains, if not our fate and fortunes, at least our bodily characteristics down to the colour of our eyelashes, it becomes a question whether the virtues of nucleic acids may not rival those of amino-acid chains in their vital importance From Steudel's figures it can be reckoned that there are about half a million molecules of nucleic acid in a single sperm cell of the species with which he was working.

And in addition to nucleic acids there are also strange compounds of higher fatty acids containing suspiciously significant groups, identical in their general character with those found also in nucleic acid—namely, phosphoric acid, organic bases, and sugar; and besides these there are the mysterious sterols All of these are frankly insoluble in water, and yet have in some part of their composition features that make them not indifferent to water or even to the molcules and ions that exist in true solution, in the liquid state, within the cell The physical condition of these insoluble substances in the aqueous system of the cell is still little understood All that can be said with certainty is that they must modify its homogeneity even more than the long floating chains of amino-acids, however much these may be linked together one with another If the characteristic behaviour of living matter is rightly regarded as due to the order that it introduces into the movements and spatial relationships of foreign molecules in its vicinity, then these insoluble components may well be expected to play a leading rôle by forming films and surfaces that permeate its texture and delimit its parts

Such an analysis of the chemical meaning of material life viewed in the light of scientific facts has to be largely an exercise of the imagination, but it may present itself as an intellectual necessity If it is right to regard the power of spontaneous self-regeneration as the distinctive property of living matter, it is not intellectually possible to be content with a phrase and dismiss it A phrase is itself an image, and an image, however shadowy, has parts and dimensions Those who feel it an intellectual necessity to explore unexplored lands cannot procure maps, but that does not justify their setting out with no forethought or reasoned plans

The beginning of life if it is an intellectual necessity to trace this, would thus appear to have been in the coming together of atoms of certain elements in such a pattern that this power in its simplest form resulted from its design Some might call this event fortuitous, others the predictable outcome of the inherent properties of those elements the inevitable operation in the course of time of the laws of chance Those who call it fortuitous may go so far as to regard the whole history of life as fortuitous, and give priority to the concurrence of the atoms over the properties and functions that are revealed by the concurrence The others may look on life as the fulfilment of the destiny of these elements, and give priority to the potential properties of matter over the concurrence which was no more than their epiphany.

SURVIVAL POWER OF CERTAIN ATOMIC GROUPINGS

If this analysis is approved and the distinctive property of living matter, the power of self-regeneration, depends upon the power of limiting the movements and directing and controlling the spatial relations of surrounding molecules so as to modify their chemical behaviour, it is the exercise of this same power that leads to the formation of substances such as starch glycogen and fats ; and in so far as such substances contribute to the regeneration of the living matter, the power of forming them contributes to its survival Where energy is necessary for such synthetic rearrangements of adjacent matter—where, that is, the rearrangement involves coercion of atoms into positions of strain in which they have the potential energy of position which we call chemical energy—this energy may be derived from the radiant energy of the sun or from the combination of oxygen with adjacent organic matter In the latter case the combination is again a manifestation of the power of ordering the disposition of surrounding molecules and directing their movements so that they behave as in other circumstances they would be but little prone to do The energy so liberated, besides contributing to the formation of new living matter or of the material to be used in its formation, may serve in other ways to promote the processes by which life is maintained. It may accelerate them by imparting increased kinetic activity or rise of temperature, or may bring about movements that are resisted by external forces, and so enable the living system to do work.

This is all merely a restatement of the commonplaces of biology necessary only as part of the attempt to correlate them physiologically with the fundamental property of that which is alive to regenerate itself at the expense of material that is not alive This faculty implies the power of introducing order into the chaotic movements of adjacent matter in conformity with patterns that it possesses It is a faculty resident in material that is capable of incalculable variation The number of permutations of its parts that are possible without affecting the results of such analysis as is practicable defies calculation Their calculation, were it possible, would lead to figures that are so large as to mean no more than the dimensions of the universe Some of these permutations confer synthetic powers which others do not When they appear, are they not what biologists call for short mutations ? But when they appear, if they retain the power of self-regeneration, and if they minister to its maintenance, they will ipso facto survive For whatever promotes persistence of this power must itself survive

A disposition of matter in molecules or aggregates, unstable and incalculably variable, that has and retains the power of determining the disposition of matter not yet so disposed in such a way as to conform to its own disposition or to patterns which help it to exercise this power is all that must be premised for the whole of evolution to follow. Variations that do not or cease to contribute to the retention of this power do not survive The condition of survival is ministration to self-regeneration, that is to the maintenance of life

Before the days of vertebrates, in pre-Silurian time, an unstable variation in the disposition of atoms and organic combinations of atoms occurred in certain types that was mainly protein in character, a protein to the making of which little short of 200 amino-acid links must contribute Coupled to this protein, which probably is not the same in all species of animals in which it is found, is another group containing iron that is probably always the same This group is of remarkable nature, and is closely related to one that occurs in the far older substance chlorophyll This complex substance hæmoglobin had the power of attaching to itself two atoms of oxygen for each atom of iron that it contained in such a way that it could be readily detached and made available for effecting oxidations. Such was the service that this variation rendered that it is safe to say that without it there could be no vertebrate creation It is this service that has made it possible for it to survive to this day, when in the human species alone it is being produced at the rate of about 10,000 tons a day. The story of the service of chlorophyll would, of course, be more remarkable than this

Natural selection applies to the survival of the chemical forms of living matter as it does to complex living organisms These forms, infinitely protean in their variety, survive and persist in so far and so long as they minister to its self-regeneration It is the principle of survival by service Function alone gives permanence to structure Structure without design is a pathological excrescence that has in itself the seeds of its own destruction. What does not minister to self-regeneration has no enduring share in life, for self-regeneration is the key to life

Why is it that what may be termed official physiology takes so little cognisance of the doctrine of evolution ? These branches of biological study appear to follow courses so exactly parallel that they never meet

The doctrine of evolution digs down into the foundations of scientific philosophy. If a physiologist addressing physiologists ventures to say anything on this subject of supreme appeal to all biologists it must be in exaltation of the work of those who have approached it from the morphological side, and it may be in hopeful anticipation of the ultimate share in the elucidation of some of its problems to be borne by physiology

PROPERTIES AND BEHAVIOUR OF CELLS

On the part that function plays in the determination of structure it is to be supposed that physiology will ultimately, at any rate, have something more to say. May I submit to the consideration of physiologists certain points in the physiological development of the machinary of the body where, unless I am mistaken, it is possible to detect the operation of function in determining the design of the machine ? The properties and behaviour of cells result from the properties and behaviour of the material composing them. When a muscle cell contracts this is, in general terms, a reversible rearrangement of its parts in response to some alteration in the distribution of forces within or about it due to a disturbance from without. Such reversible reaction to adequate disturbance is a property common in the material of which living cells are composed. In addition to this reversible type of reaction there are irreversible reactions which are characteristic of other kinds of cells, and it is what we call connective-tissue cells that I would ask you to consider There are several kinds of connective-tissue cells, but they are alike in that they produce and discharge into their vicinity material of a characteristic composition ; in some of the commonest this material is chemically collagen, the substance out of which gelatin can be obtained In course of time these cells come to be embedded in the material which *they deposit about themselves* and so form one kind of connective tissue Cells capable of behaving in this way are found however, which have not yet exercised their faculty, these fibroblasts are then undifferentiated wandering cells that have found no abiding place in the community in which they have their birth What it is that makes them settle down and start producing the material in which they come to be embedded has never yet been determined. But the most striking structures to which they give rise are the tendons and aponeuroses that make the muscles fast to the bones, and the ligaments that bind the bones to one another The material that they deposit is composed of inextensible fibres that lie in the case of tendons, at any rate so exactly and exclusively in the line of the resultant of the tensions set up in the muscle to which they attach themselves, that it is difficult to believe that the disturbance which starts them producing their characteristic secretion is anything else than the pull exerted on them by the muscle-fibres to which they are attached, the recurring external disturbances that produce reversible states of tension in the muscle, indirectly producing in them an irreversible reaction, which consists in the discharge of material that by its inextensibility can transmit the tension along the line of the force that provokes its deposition In their simplest form cells of this kind deposit the wavy fibres in areolar tissue which, when straightened out under the action of a displacing force, set a limit by their inextensibility to the dislocation of the part first affected, and so distribute the action of the displacing force over surrounding areas It is interesting to note that the origin of cells of this kind has been traced to the mesothelium cells that line tissue spaces and serous cavities, the clefts that make the gliding displacements of parts over one another possible The deposition of fibrous material seems here, as in the tendons and ligaments to be the result of reaction to the recurring disturbances set up by displacements, such, for instance, as those of the lungs, the alimentary tract, the heart and pulsating vessels, and the deposition occurs in the line of strains set up by the displacing forces The service rendered by this behaviour of the cells is that the fibres which they deposit, in virtue of their inextensibility, limit the extent of displacement at any one point by distributing it to surrounding parts

The other component of areolar tissue, the elastic fibres, is similarly produced by other cells These fibres take a straight course between their attachments, displacements in the line of their deposition are rendered possible by their stretching, and are recovered from by their elasticity

The contribution made by such cells to the fabric of the body appears to result from the recurring operation of disturbances, to which they react by depositing fibres along the lines of disturbance

FORMATION OF THE SKELETON

More striking are the properties of cells upon which the formation of the skeleton depends The cells that make bone not only secrete fibrous collagen, they also encrust the fibres with insoluble lime salts, and it has long been subject of comment that the rigid bone that results always comes to lie in the line of prevailing strains and stresses The analysis of the structure, for instance, of the head and neck of the human femur, by Wolff and others who have followed him, shows how strictly this is true Calculations prove that no particle of bone lies anywhere but where the strains dictate We can predict with certainty it seems, that it will be found that bone cells are composed of material that in reacting to physical forces directs, in constant relation to the line of action of those forces, the deposition of the substances which make up this connective tissue Bone can only arise where strains and stresses set up this reaction, and the greater the strain or stress the denser the deposit When a bone is fractured many bone cells are dislodged, and in the abundance of nutriment that ruptured vessels supply, these cells released from their imprisonment, multiply At first the force of gravity and the twitching of muscles acting on the soft semi-fluid tissues between the broken ends of the bone supply stimuli that are indeterminate in direction, and such reaction as occurs results only in the formation of loosely ordered calcareous fibres, but even this soft callus gives some degree of rigidity, sufficient to restrict the strains gradually to more and more clearly defined lines along which in proportion a stronger reaction can take place Once it is established that bone corpuscles react to strain and stress by discharging collagen, the intimate spatial disposition of which, as well as of the lime salts with which it comes to be encrusted is determined by the directing forces to which it is exposed, and once it is recognised that the law of spontaneous regeneration requires that this reaction will persist in proportion to the prevalence of these forces, not only must the gradual replacement of callus by appropriate permanent bone necessarily follow, bone in which no particle persists except it be in the line of constantly recurring stress and strain, but it will also necessarily follow that the position of every spicule of bone in the skeleton, cancellous or compact, is the expression of a physiological reaction to the forces of gravity and muscular tension The evolution of the machinary of the connective tissues seems to be not entirely the result of natural selection and the survival of individuals in which this machinery chanced to be of appropriate design The appearance in early vertebrates of the material that is characteristic of the bone corpuscle seems to have ensured that skeletons would take a shape determined by the direction of the forces to which these corpuscles were exposed, and that the formation of this skeleton is as much a reaction to recurring stimuli as are the reflexes, composite movements and postures characteristic for the species

This conception of the way in which the vertebrate connective tissues take their shape transfers a large share of the development of the bodily form back into the nervous system, in which the machinery is stored that directs and determines the habitual movements and postures that in reaction to external disturbances are specific A physiological account of the evolution of the nervous system, one certainly that is based on the chemical constitution and chemical behaviour of its component parts, must seem almost infinitely remote from practical investigation But the work of Pavlov has made one thing clear, that by a physiological reaction in it machinery may come into existence which did not exist before The repeated occurrence of a disturbance at times that are uniformly related to the normal operation of existing machinery results in the acquirement of a new reaction which must require machinery that is new It is rendered probable, if not proved, that this new machinery is situated in what may be called the growing point of the central nervous system, the cortex of the cerebral hemispheres, the part where all is not cut and dry, where cells retain more of the properties of the developing neuroblasts, the properties that enable them to grow out through the embryonic tissues along courses that make it certain that the maturing organism will behave in a manner true to type In the formation of a conditioned reflex two events are made to occur in the cerebral cortex at times which are uniformly related to one another, one of these events, from the constitution of the nervous system, necessarily results in a certain activity of some muscle or gland, the other has been hitherto in no way related to such a result; after many repetitions of the association of these events it is found that that one which previously had never resulted in this particular activity, comes to have this result as certainly as the other

The sight and smell of food in any hungry animal results in the secretion of saliva because the cells to which the effect of these visual and olfactory stimuli is referred are anatomically connected with cells that set the salivary gland in action, the cells on which some particular sound takes effect are not anatomically connected with them and this particular sound has therefore no effect upon them But with the establishment of the conditioned reflex the anatomical connexion comes into existence As a result of a functional reaction of nerve cells to disturbances in other nerve cells with which they were not previously anatomically connected, a structure appears which is indistinguishable so long as it lasts from the structures that constitute any other reflex arc. The conditions that determine its persistence or effacement have been, and are being, studied as thoroughly as were those which allow it to appear. The outcome of these studies must be of incalculable importance in evolutional physiology. They are being watched with the keenest interest doubtless by all biologists, but more especially by those who believe that physiology has to take a much bigger part in the solution of some of the fundamental difficulties of biological science than it has been able to take in the past.

EVOLUTIONAL HISTORY OF LIFE.

But if and when it is possible to trace the origin of structures to functional reactions of cells and to reactions that depend upon the chemical properties of the cell substance; and if and when this is possible not only in the connective tissues, but also in the nervous system, the functions of which have so controlling an influence on the operation of every part of the body; until it becomes clear that the results of changes in such influence reappear in succeeding generations, the study of functions can have no bearing upon the ultimate problem of biology, the evolutional history of life upon the earth. Pavlov communicated to the last International Congress of Physiology in 1923 some results of experiments that he had done upon this subject which, when confirmed, would electrify the atmosphere. Conditioned reflexes that are established only after many—80 or 100—repetitions of the associated stimulus, in each succeeding generation require fewer and fewer repetitions and in the fourth may be established after only four. In April of this year he wrote to say that owing to other work he had not been able to give the necessary time to confirmation of these results. We are content to wait.

In the great question whether characteristics developed in the life of an individual have any influence on descendants, experimental evidence must come slowly. In what is called parallel induction a step has been taken which is probably of greater importance than is generally conceded. External influences that affect the bodily characteristics of an organism affect also the germ plasm in such a way that these characteristics appear in the first, and even in a less degree, in the second generation, born after the external influences have ceased to operate. While such experiments furnish evidence only of a temporary change in the properties of the germ plasm, one that may be put down to the lodgment in it of unassimilated foreign matter that is gradually eliminated, the fact that the eternal germ plasm has been shown to be subject to temporal influences must not be belittled. A true mutation is not eternal. Our descendants may be able to dispense with hæmoglobin. Whether the hereditary melanism that in certain moths it is said can be induced by food infected with manganese is something more than such parallel induction, I hope there may be some present who can say.

Physiological inquiry is a stream that has many sources; its waters gather from quarters far removed from one another. A marvellous meeting took place in the early years of this century when the forgotten experiments of Mendel came to the surface again, and found corroboration in the cytological studies that from about the same time had pursued their slow obstructed way above ground in the endeavour to elucidate the changes in the nucleus of maturing germ cells. In a resting germ cell the chromosomes form an even number, characteristic for the species; they consist of half that number of pairs of homologues, one of each pair descended from the paternal element in the last zygosis, the other from the maternal. At one of the cell divisions by which the germ cell gives rise to the mature gamete, with half the characteristic number of chromosomes, there occurs a segregation of the two members of each pair so that they pass into different gametes; the exact cytological equivalent of Mendelian segregation of allelomorphic pairs of characters. To-day the study of genetics and of the topographical anatomy of the chromosomes, with its groupings and crossings over,' seems to call out for chemical assistance. It may be that in the lifetime of some of us those confluent streams of thought and experiment are to be joined by yet another that rises in the vast remote, and, as it must appear to some, muddy swamps of physiological chemistry; and it then, forgetting its 'foiled, circuitous wanderings," will form with them a 'majestic river, brimming and bright and large.'

A STUDY OF
SPRUE AND ADDISONIAN ANÆMIA.

By H. B. NEWHAM, C.M.G., M.D. DURH.,
M.R.C.P. LOND.,
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE;
AND
R. M. MORRIS, M.B., B.S. LOND.,
LATE HOUSE PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES.
WITH CONCLUSIONS BY
P. H. MANSON-BAHR, D.S.O., M.D. CAMB.,
F.R.C.P. LOND.,
PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES.

IN the present study an attempt is made to emphasise some points in connexion with sprue with reference to Addisonian anæmia, as it is felt that the differential diagnosis is often a difficult matter in individual cases.

The subject is treated from two points of view: that of the clinician, and secondly, of the hæmatologist. From the clinical aspect sprue presents certain cardinal features, described by Low[1] thus: "loss of weight, diarrhœa with white frothy stools, tongue and mouth lesions, anæmia, and shrinkage of the liver," but it is in only a proportion of cases that all these points are manifest.

Three groups of cases may be distinguished: (A) With marked gastro-intestinal and mouth symptoms but without noteworthy anæmia. (B) With gastro-intestinal and mouth symptoms and accompanied by definite anæmia. (C) With recurrent attacks of mild gastro-intestinal or mouth symptoms and severe anæmia. This group is somewhat small and is more or less confined to chronic cases in older patients.

In the present paper it is not intended to deal with Group (C).

In order to arrive at the approximate number of cases falling into Groups (A) and (B), 90 cases of sprue have been taken, all treated in the Hospital for Tropical Diseases, London, between the years 1920–25. Of these, it is found that 45 presented a blood count of less than 4,000,000 red corpuscles and can therefore be included in Group (B).

It is interesting to note the remark of Gulland and Goodall[2] when discussing Addisonian anæmia: "Diarrhœa may be the main symptom and we have seen cases in which the diagnosis of . . . sprue . . . had been made before the blood was examined." This illustrates the difficulty but does not give the solution. There are several points in common between the two diseases, especially in the type of Addisonian anæmia with alimentary symptoms.

Ætiology.

In both diseases a causative agent has been incriminated, in neither is its guilt proven. In both it is thought primarily to attack the alimentary canal.

The *sex-incidence* in Addisonian anæmia is given as 2 males : 1 female (Thursfield,[3] Tidy[4])—in the present series of 90 cases of sprue 59 were males and 31 females—thus giving approximately a ratio of 2 : 1. This ratio is not absolutely trustworthy, as the accommodation for female patients during half the period under review was extremely limited. The general impression gained is that females predominate.

The *age-incidence* of sprue, males show an average age at onset 42 years (extremes 22 and 68) and females 40 years (extremes 20 and 62); again these figures compare closely with those usually accepted as obtaining in Addisonian anæmia

The occurrence of *familial or hereditary cases* in Addison's anæmia has lately attracted much attention (Hurst),[5] and in sprue Manson-Bahr[6] quotes cases in husband and wife, whilst in the present series is a severe case of sprue occurring in a man, whose mother had died of sprue in India some years previously

A striking difference between the two diseases is seen when the *geographical distribution* is considered Addison's anæmia has a world-wide sway, whilst sprue is peculiarly limited to certain areas

The 90 cases under review reveal the following India (46), South China (15), Malaya and Ceylon (7 each), Burma and the Philippines (2 each), and Brazil, Nicaragua, Palestine, and the West Indies (1 each), as well as a remainder of 7 seamen who have spent much time in Far Eastern seas The length of residence in these areas varied from 19 months to 48 years In 10 cases the disease did not develop until the return of the patient to this country It is extremely doubtful whether sprue ever occurs indigenously in Great Britain

Whilst sprue is fairly frequently seen, it is necessary to sound a warning against too readily diagnosing it in anæmic patients with diarrhœa on their return from the tropics, who may be cases of true Addisonian anæmia

Wherein, then, lie the distinguishing features? Taking the 45 cases showing anæmia, the differences may be given under the headings of (1) type of onset, (2) symptoms and physical signs, (3) course of the disease

Type of Onset

In Addisonian anæmia, the onset is notoriously insidious, but in 19 of the sprue cases it was sudden, in 7 of these occurring in the course of some other condition—viz, pregnancy or puerperium 4, dengue 2, acute intestinal amœbiasis 1 When coming under observation the disease had been in progress for periods from two weeks to seven years

Symptoms and Physical Signs

The outstanding symptom of sprue—diarrhœa—was present in all the 45 cases, and at some stage of the disease could be accurately described as consisting of copious, white, frothy, liquid, or partially liquid, stools, having a characteristic odour, sour and disagreeable There is a marked tendency for this to occur in the morning, but in a few cases it was limited to the afternoon The number of stools per day ranged from 1 to 12

Cabot[7] states that diarrhœa was present in 60 per cent of his American cases of Addison's anæmia, but gives no details as to the character of the stools Gulland and Goodall[8] speak of "chrome yellow diarrhœa," whilst Schneider[9] has been at great pains to demonstrate the increase in pigments in both fæces and urine in Addisonian anæmia In a somewhat limited experience of the latter disease, we do not recall a case showing stools in any way resembling sprue

Of the *sore mouth and tongue*—present in 38 of these cases—it is necessary to treat in greater detail, owing to the prominence given to this feature in Addisonian anæmia by Hunter, to the extent of suggesting an alteration of terminology[10]

This authority describes numerous cases of Addisonian anæmia with glossitis[11] from which may be quoted —

1 In early stage "great tenderness on mastication when hot foods are taken Tongue raw and flabby red and fiery with smooth patches" Lesions "extending to anterior pillar of fauces" Six months later "tongue free from papillæ . fiery redness inflamed vesicles"

2 "Small round vesicles on edges of tongue, &c, leaving whitish spots with a zone of congestion"

3 "Tongue raw and fissured a deeply drilled-out ulcer on tongue"

The points he appears to stress are the extreme redness of the tongue before the anæmia becomes too severe, the occurrence of glossitis in the *early* stages and the remarkable periodicity (Fig 1)

Carnegie-Brown[12] states that the earliest change in acute cases of sprue is a diffuse inflammation, especially involving the fungiform papillæ, with the occurrence of yellow vesicles—aphthæ—in crops at irregular periods and spontaneously subsiding Later changes destroy the filiform papillæ giving the appearance of prominent bright red swollen fungiform papillæ on a smooth glazed tongue Should the disease be further prolonged, even these papillæ are involved and appear as if shaved off and have a glazed flat surface (Fig 2) Cracks and fissures make their appearance and, with the recurring crops of aphthæ, complete the picture Dutch authors—De Langen and Lichtenstein[13]—in their account are in close agreement with this In our cases examples of practically all these stages were noted

In distribution the lesions included the tongue, particularly the tip and sides, the floor of the mouth, the buccal mucosa, the pillars of the fauces, and the uvula Favourite sites are the inner aspect of the lower lip and the vicinity of the lingual frenum

The aphthæ characteristically occur in crops Each crop usually consists of many aphthæ, but may be represented by a single aphtha only In one case 41 vesicles were present at the same time, and in others with sore mouths no definite vesicles were ever seen In size they varied from less than pin-head to ¼ in in diameter After lasting from one to seven days they disappeared, but in one severe case rupture of the vesicles produced several ragged superficial ulcers up to ¼ in in diameter In some the tongue was pale and thin, with glazed areas and with a tenderness out of all proportion to the slight degree of excoriation patchily present, but in these a lens often showed the flattened fungiform papillæ in large numbers These same papillæ were more often to be seen with the naked eye as prominent hyperæmic and swollen red dots on the surrounding pale expanse. In no case could the tongue have been described as "fiery red" The relation of the sore tongue to the diarrhœa is not easily made out—in some cases the two symptoms definitely alternated, in others the severest phases of each coincided

From this it will be seen that the phenomena cannot be used in a differential diagnosis We recall Hunter's own warning[14] that the glossitis he describes is only specific when accompanied by a "definite clinical picture of Addisonian anæmia"

Abdominal flatulence, especially severe before the bowels are opened, is a most distressing symptom in sprue, and occurs with a frequency—40 cases in 45—quite unknown in Addison's anæmia, similarly *œsophageal pain*, or a pain referred to the mid-sternal line brought on by swallowing even fluids (16 cases), is rare in the other disease, although Hunter[15] refers to a similar pain in a case of Addisonian anæmia It is presumably due to the extension of the oral condition down the alimentary tract

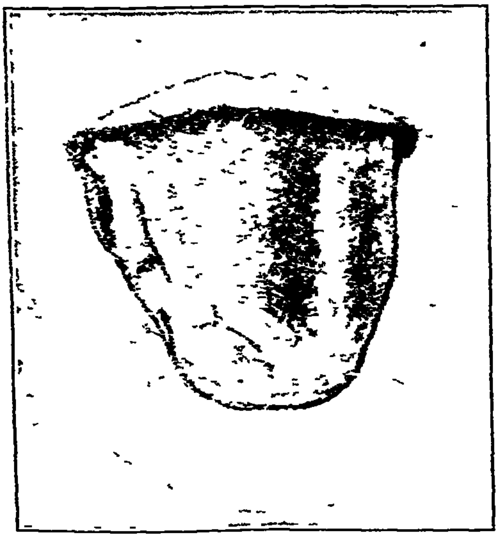
Vomiting (11 cases) and *anorexia* (10 cases) are present in sprue, but are perhaps more common in Addison's anæmia, which also applies to *loss of energy* (8 cases) as a prominent symptom

Alteration of temperament is not frequently noticed in Addison's anæmia, but no less than 12 cases of the present series themselves complained of their increasing irritability and unreasonableness and in the majority of the others their friends had made similar observations This change is often *most* apparent, and the return of good humour may be used as an index of a return to better health

Sensations of *cramps* in the lower limb muscles (6 cases) may be complained of in both diseases and are probably the result of anæmia *per se*, but of an essentially different character is the occasional appearance of *tetany* (3 cases) This probably *does* not occur in Addisonian anæmia *Loss of weight* was apparent in 43 out of the 45 cases and is a most valuable distinguishing feature, especially in its severity—a loss of 2 to 4 st. in weight in less than one year being not uncommonly recorded On an average in a moderate case with anæmia it may be given as about 1 st. should treatment have been delayed for as long as six months. It is this feature which is responsible for the emaciated appearance of so many of the patients, and provides a guiding contrast to the plump sufferer from Addison's anæmia Pari passu the *skin* seldom (2 cases in 45) shows any tendency to lemon tinting, but is more characteristically dry and wrinkled, with a dull, earthy tinge like that of chronic intestinal stasis.

Pyrexia occurs (10 cases) in sprue as in other severe anæmias. It may reach 103° F and be distinctly prolonged. The *abdomen* in sprue at once attracts attention the wall is invariably thin and often distended with especial prominence in the sub-umbilical area. Percussion gives a tympanitic note well into the flanks The tenuity of the wall may be such that peristalsis becomes visible (7 cases) Rogers [16] states that the liver may be enlarged in the early stage and that it then shrinks, but by the time the patients were seen this initial enlargement was not found, not even in a case with acute onset two weeks before

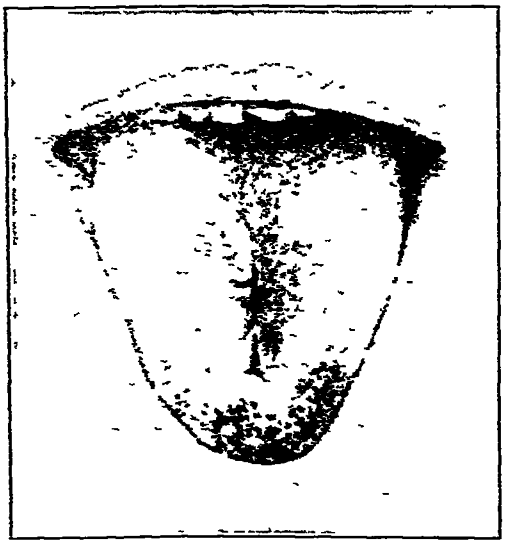
FIG 1.



[*Philip Manson-Bahr pinx.*

The primary glossitis of Addisonian anæmia Note the general destruction of papillæ, the raw surface on the dorsum of the tongue The general glossy appearance and the superficial fissuring at the periphery of the organ.

FIG 2



[*Philip Manson-Bahr pinx.*

The primary glossitis of acute sprue Note the aphthous ulceration at the tip of the organ, the atrophy of the filiform papillæ in the immediate vicinity, and the inflammation of the fungiform papillæ. There is superficial central fissuring.

In no less than 40 of our cases, the *liver dullness* as measured in the right mammary line was definitely diminished Cabot [17] notes enlargement of the liver in 35 per cent. of his cases of Addison's anæmia but does not mention diminution in size. The same authority notes enlargement of the spleen in 27 per cent. of Addison's anæmia. In no case of sprue was this feature found, except temporarily in one undergoing treatment, when a relapse of benign tertian malaria occurred as a complication The cardiovascular system presents the features to be expected in a severe anæmia—poor cardiac sounds hæmic murmurs and a low blood pressure Organic disease of the central nervous system, such as subacute combined degeneration, is as yet unknown in sprue. With reference to sprue de Langen and Lichtenstein [18] state there is no typical picture of gastric function; sometimes normal free acid is present, sometimes hyperchlorhydria or again achlorhydria Fractional test-meals in five of the cases under review yielded achlorhydria in two hypochlorhydria in two, and hyperchlorhydria in one—this latter without other demonstrable cause It is almost superfluous to recall the practically invariable achlorhydria of Addison's anæmia.

Course of the Disease.

In Addison's anæmia repeated and superficially complete remissions have always been accepted as characteristic; such peculiar periods of freedom from symptoms were apparent in 22 out of our 45 cases of sprue usually, but not always, after strict dietetic treatment. The length of the remission varied from three months to ten years—in this latter case "reinfection" may have occurred as the whole period was spent in India. The importance of the correct diagnosis is manifest when the question of therapeusis is considered In Addison's anæmia, arsenic, usually given by the mouth is our sheet-anchor with the acid treatment (Hurst) [19] as an adjuvant: in sprue, of the former all observers agree on its harmful effects, and of the latter, no one has produced any evidence of its efficacy In both diseases blood transfusion is valuable, and its benefits are certainly more likely to be permanent in sprue.

Prognosis

This is a difficult topic as it is not now possible to trace most of the cases of this series. Seven of these died the rest left hospital considerably improved and in most instances free of symptoms with regained weight—in one case 3 st. in 12 weeks' treatment. Seven of these last are known to be still free of any signs or symptom of sprue after a period of two and a half years. In a few others the disease, whilst not eradicated is under control and causes no trouble

The Blood in Sprue.

The degree of anæmia associated with sprue may vary very considerably in different cases. One may have a very severe degree of anæmia where the symptoms of the disease in the alimentary system are not very severe On the other hand the most marked alimentary disturbance may be associated with only a moderate amount of anæmia. Generally speaking, however, in the majority of cases of severe sprue, and especially if it has been of considerable duration the anæmia is grave.

Of 12 cases of well-marked sprue (7 male and 5 female) which have recently been under treatment at the Hospital for Tropical Diseases and whose blood has been closely studied, the accompanying table (I) shows the main points in the composition of the blood when first coming under our care The duration of the disease is reckoned from the onset of symptoms to the date of admission to this hospital The differential count is based on a count of 500 leucocytes, and the percentage of hæmoglobin has been estimated by Van Slyke's gasometric method

The blood picture associated with the anæmia of sprue has been described by various authorities as being very similar to that obtaining in Addisonian anæmia Thus Nolen[20] states that it is sometimes impossible to distinguish sprue from Addisonian anæmia In some of his cases of sprue he found the complete blood picture of Addisonian anæmia, in others only the high colour-index

Manson-Bahr[21] and Low[22] also quote cases of sprue with blood pictures similar to Addisonian anæmia This is borne out by the figures in the chart, especially the commonly high colour-index, the leucopenia, relative lymphocytosis, presence of nucleated red cells (the number quoted is that obtained in doing a differential count of 500 leucocytes), and the marked anisocytosis and poikilocytosis

Just as these more marked features vary considerably in cases of true Addisonian anæmia so similar variation is to be noted in cases of sprue anæmia As regards colour-index, all of our cases, with the exception of two, give a figure exceeding 1 0, the highest figure recorded being 1 44 Of the two instances in which a figure below 1 0 has been recorded Case 6 shows only a very moderate degree of anæmia, but in Case 11 a most profound degree of anæmia is present but with a low colour-index Just as in true Addisonian anæmia a high colour-index is the general rule, well authenticated cases of that disease have been observed in which an index below 1 0 was obtained

So in the anæmia of sprue, when well marked, it is usual to get a figure of more than 1 0 Still, cases do occur from time to time even when the anæmia is profound when a figure below 1 0 is found Leucopenia to a greater or less extent seems to be a very common feature of sprue anæmia, and this decrease in the white cells seems to run more or less pari passu with the decrease in the red cells Relative lymphocytosis appears to be a common feature in sprue anæmia as in Addisonian anæmia

TABLE I —SHOWING THE CONDITION OF THE BLOOD IN 12 CASES OF SPRUE

Case No	Date in 1925	Duration of disease	Hæmoglobin (Van Slyke) per cent	Red cells per c mm	Colour-index	Leucocytes per c.mm	Lymphocytes per cent	Large mononuclear per cent	Polymorphonuclear per cent	Eosinophiles per cent	Nucleated red cells per 500 leucocytes	Anisocytosis	Poikilocytosis
1	25/6	4 y	40 7	1,620,000	1 2	4000	52	1 0	46	1 0	2 normo 2 megalo	+ + +	+ + +

Remarks —CASE 2 Patient had slight ankylostomiasis CASES 10 and 11 Hæmoglobin estimated by Talquist's scale Died a few days later

Progress of the Anæmia

The course of the anæmia appears to depend on the response to treatment of the sprue condition If by suitable dietetic measures the alimentary disturbance is improved, so the degree of anæmia will be lessened, and in many cases of severe sprue with a profound degree of anæmia in which the patient makes a good response to sprue treatment the improvement in the anæmia is both marked and rapid One of our cases, who on admission had a red cell count of 1,620,000 and hæmoglobin 40 7 per cent., six weeks later showed an improvement to 4,000,000 red cells and 80 per cent hæmoglobin on dietetic treatment alone

It is realised that an improvement in the blood condition comparable to this may occasionally be seen in cases of true Addisonian anæmia but is by no means of common occurrence More commonly the blood will improve slowly up to a moderate degree, and either remain at that stage or more usually relapse again Moreover, the relapses in Addisonian anæmia are commonly rapid in their onset, whereas in the anæmia accompanying sprue, if relapse occurs, it is gradual, and accompanied by a recrudescence of the sprue symptoms, the anæmia gradually increasing as the sprue manifestations become more severe

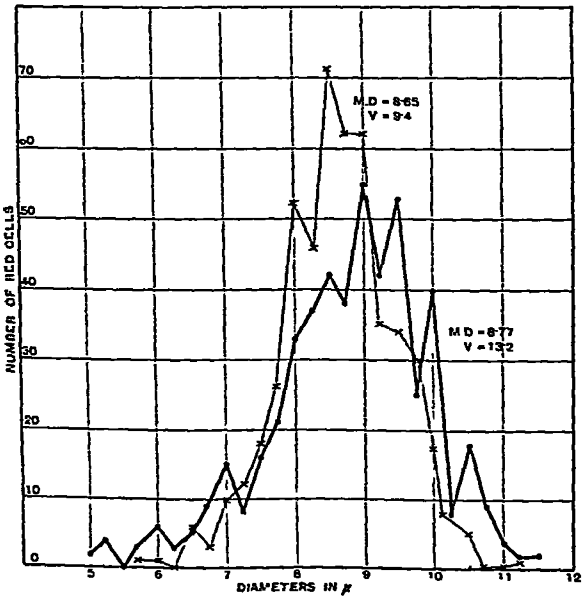
Scott has recorded two cases[27] in which sprue patients died of Addisonian anæmia, so that both diseases can apparently occur concurrently

Price-Jones Curves

Price-Jones's graphic method of recording the size of the red blood corpuscles has proved of marked value in the study of cases of Addisonian anæmia He has shown that by accurately measuring 500 red blood cells, and charting the number of each size, the size being shown horizontally and the number vertically, a curve can be obtained which differs very markedly whether normal blood, Addisonian anæmia blood, or blood showing secondary anæmia be studied In normal blood the variation in the size of the cells is not very marked, and a uniform curve is obtained with a sharp peak and with a narrow base In the case of Addisonian anæmia the whole curve moves to the right, is very irregular, and has a wide base, owing to the marked variation in the size of the individual cells On the other hand, the curve obtained with blood from a case of secondary anæmia more closely approximates to that of normal blood, but the base of the curve is usually somewhat wider and there is a "shift to the left" of the peak of the curve We have applied Price-Jones method to our study of the anæmia associated with sprue in ten of our cases, basing our results on an accurate measurement of 500 red cells in each instance In only three instances of these ten cases are curves obtained approximating to those seen in Addisonian anæmia, but even these do not exhibit the marked irregularity and widely extended base of the curves in Addisonian anæmia A chart is appended showing the curve obtained in Case 1 (Fig 3)

In the chart of this case two curves are superimposed The one was made when the red cell count was 2 600,000 per c mm and the second when this had risen to 4,100,000 It will be seen that a definite change in the character of the chart has taken place, a "shift to the left" of the highest peak having occurred, whilst the base has contracted somewhat and the whole curve becomes more regular

FIG. 3



M.D =Mean diameter V =Coefficient of variation.

Hurst[24] states that the characteristic curve of Addisonian anæmia is seen in that disease even before the patient is markedly anæmic and also during remissions, and in the figure he publishes (from Shackle and Hampson[25]) in which two curves from the same patient at intervals are shown, in both instances the curves have the characteristic irregular outline and broad base It would appear, therefore, that although in the anæmia of sprue the Price-Jones curves obtained in the severer cases approximate to those seen in cases of Addisonian anæmia the degree of variation in size of the red cells in the former disease is not spread over so wide a range, and the base of the curve tends therefore to be somewhat more restricted than in the latter condition

Cholesterol Content of Blood

It has been noted by several observers, notably Bloor,[26] Myers,[27] Pacini,[28] &c, that the cholesterol content of the blood is distinctly lowered in cases of anæmia and various analyses have been made of the cholesterol content of the blood in Addisonian anæmia, but we have not come across any similar figures for the anæmia accompanying many cases of sprue

It was considered worth while, therefore, to carry out a series of analyses on some of our cases of sprue, and the results are appended in the accompanying Table II

There appears to be some divergence of opinion as to the cholesterol content of normal blood Myers[29] gives it at about 0 160–0 180 per cent, whilst Bloor[30] gives somewhat higher figures In an investigation of the cholesterol content of the blood of seven healthy adult men which we carried out, we found that the figures for the cholesterol content of the plasma varied between 0 200 and 0 140 per cent., giving an average of 0 192 per cent, whilst for the washed corpuscles the figures varied between 0 155 and 0 122 per cent with an average of 0 140 per cent. Grigaut,[31] in an analysis of the blood of four normal individuals, gives an average of 0 171 per cent for plasma and 0 140 per cent. for corpuscles In all our investigations on the cholesterol content of blood Myer's method of chloroform extraction with subsequent Lieberman-Burchard colour development and estimation by the colorimeter was employed.

We have in all carried out cholesterol estimations in 11 of our cases of sprue anæmia (Table II)

It will be seen that in all the cases of anæmia accompanying sprue there is a definite hypocholesterolæmia especially well marked in several cases, and that the degree of such hypocholesterolæmia seems to bear little or no relationship to the degree of anæmia present Myers, in an analysis of two cases of Addisonian anæmia by his method, gives figures of 0 065 and 0 065 for plasma and 0 12 and 0 13 for washed corpuscles It is thus apparent that no distinction can be drawn between Addisonian anæmia and the anæmia of sprue based on cholesterol content of the blood

TABLE II.

Case	Red cells per c mm	Hæmoglobin per cent	Cholesterol.	
			Plasma per cent	Corpuscles per cent
1	1,620,000	40 7	0 150	0 113
2	3,900,000	86·0	0 177	0 044
3	3,700,000	85 6	0 060	0 066
4	2,150,000	62 0	0 116	0 136
5	1,100,000	24 0	0 037	0 150
6	4,000,000	78 5	0 153	0 125
7	3,730,000	94 6	0 093	0 103
8	3,500,000	92 8	0·066	0 065
9	2,920,000	75 0	0 160	0 144
12	2,470,000	66 5	0 136	0 113

Blood Group

Hunter,[32] in his observations on 42 cases of Addisonian anæmia under his care, investigated the blood groups of 38 of his patients and found that of these individuals 34 belonged to Type II., 3 were of Type IV, and 1 of Type III These figures are according to the Moss classification and show a marked predominance of Type II individuals, but whether or no any significance should be attached to this large number of Type II cases was not determined In 9 of our cases of sprue the blood group was determined, 6 of these (4 men and 2 women) came under Group IV, 1 male belonged to Group I, 1 female to Group II, and 1 man to Group III The great majority of our cases, therefore, came under Group IV but the total number of cases is much too small to warrant any deductions being drawn

Van den Bergh's Reaction.

It is generally conceded that in the acute cases of Addisonian anæmia the application of Van den Bergh's reaction to the blood serum almost invariably gives a positive indirect reaction, but that in the well-marked remissions in this disease this reaction may become very poorly marked or even disappear to reappear on the occurrence of a relapse. In 7 of our cases of sprue (3 men and 4 women) this reaction was carried out, and all but one showed a positive indirect reaction The strength of the reaction seemed to depend on the degree of anæmia present, those cases with a very marked degree of anæmia giving a well-marked reaction, whilst those with only a moderate loss of red cells only displayed a very feeble reaction It would appear, therefore, that the anæmia of sprue follows closely in this respect the behaviour of Addisonian anæmia blood.

Conclusions

1. Sprue and Addisonian anæmia are two distinct clinical entities; though having several features in common we think they are produced by two definite and distinct ætiological agents.

2 Sprue is definitely a disease of the tropics, in some way connected with the exposure of susceptible individuals to a condition, or conditions, inseparable from life in a tropical climate, but it is probable that these conditions are more effective in some tropical countries than in others, and in some such manner we may explain the absence of indigenous sprue from Central Africa Addisonian anæmia, on the other hand, has a cosmopolitan distribution

3 The typical anæmia which accompanies these two diseases is almost identical, but this feature alone does not indicate a similar, or even allied, ætiology

4. Addisonian anæmia is generally a fatal disease, though it may run a prolonged course, sprue is by no means so That in the latter absolute recovery can ensue is a matter of common knowledge The facts assembled in this paper suggest to us (*a*) That the sprue anæmia is secondary to the gastro-intestinal lesions (*b*) In Addisonian anæmia, the anæmia is due to disease of the blood-forming organs so that recovery is not dependent on the processes of digestion and assimilation; the glossitis and gastro-intestinal symptoms appear to be secondary to, or to follow on, the primary anæmia (*c*) In sprue assimilation of food is fundamentally affected, with the production of great emaciation and loss of body-fat in which all organs, especially the liver, take part and which is dependent upon, and associated with, the excretion of one-quarter (it may be) of the food taken by the mouth; consequently, the excretion of large, fatty, and colourless stools constitute a feature which is pathognomonic of sprue (*d*) In Addisonian anæmia assimilation of food is not affected to the same degree, emaciation is, therefore, not a feature; an increase of body-fat may actually accrue, there is no wasting of the internal organs, the stools are of normal size and appear to contain the normal amount of pigment (*e*) The toxin of Addisonian anæmia has a most definite selective action upon the peripheral nerves and central nervous system, with the production of neuritis and of spinal sclerosis, features which, in our experience, are not found associated with the anæmia of sprue

We desire to tender our grateful thanks to Dr G C Low for permission to study the records of his cases and for facilities granted to investigate the blood of patients under his care in the Hospital for Tropical Diseases

ELONGATION OF THE PELVIC COLON AND ITS SURGICAL TREATMENT

BY E. G. SLESINGER, O B E, M S LOND, F R C S ENG,
ASSISTANT SURGEON, GUY'S HOSPITAL.

THE pelvic colon varies in length between considerable limits in perfectly healthy individuals, and is relatively much longer in the infant than in the adult The following remarks are therefore not intended to suggest that elongation of the pelvic colon necessarily results in the production of symptoms, but rather to point out that in certain cases such elongation produces results sufficiently severe to call for relief, and to indicate an operative procedure which, in the four cases cited, has been followed by satisfactory results It would seem probable that this measure is indicated in a considerable proportion of cases of constipation of a certain type or, at any rate, deserves consideration as an alternative to prolonged and not invariably successful medical treatment

In the normal individual the rectum does not ordinarily contain fæces, which are prevented from entering it partly by the tonicity of the pelvi-rectal sphincter and partly, or perhaps mainly, by the angulation between the pelvic colon and the rectum—the pelvi-rectal flexure As the pelvic colon fills with fæces, which it does from below upwards, it rises into the abdomen and straightens out the pelvi-rectal flexure, allowing fæces to enter the first part of the rectum and so setting in train the defæcation reflex

It appears probable that in cases where the pelvic colon is elongated, either as a congenital abnormality or as a result of prolonged constipation of a type to be presently discussed, as fæcal material accumulates in this coil of bowel it no longer straightens out the pelvi-rectal flexure, partly because of its length, and partly because, being seldom completely evacuated, fæces no longer accumulate from the distal end Efforts to evacuate this loaded loop will tend to increase the flexure by driving the pelvic colon farther into the pelvis, with consequent increasing constipation

Sir Arbuthnot Lane has for many years pointed out that the normal reaction of the body to the presence of a constipated, loaded colon is the development of avascular bands on the surface of the outer side of the mesentery, whose function it is to support the loaded portion of the intestine and to take the strain off the sensitive mesentery. The first situation in which such bands develop is on the outer side of the iliac and pelvic colons, and in the first instance their function is beneficial They are a reaction to the assumption of the erect posture, and prevent the constipated pelvic colon from prolapsing into the pelvis Over-development of these bands is, however, exceedingly common, and if this occurs they become attached to the bowel at its anti-mesenteric border, and, by producing torsion in its long axis, lead to obstruction to the passage of its contents

"The Last Kink"

Under these conditions Lane has termed the pelvic bands the "last kink" In the presence of a well-developed "last kink" it is unusual, as one would expect, to find a very long pelvic colon, since the presence of the "kink" prevents the elongation of the bowel In certain cases, however, where the "last kink" is not well developed, and in some in which it has not formed at all, the stagnation of fæces in the pelvic colon results in marked elongation of this part of the bowel The more it becomes elongated the greater is the difficulty in emptying it, and a vicious circle results In these cases, and in the far less common ones in which the pelvic colon is congenitally elongated, it appears a rational procedure to remove the redundant bowel and to restore the colon to its normal condition, in which there is only a small reservoir between the iliac colon and the rectum By this means the pelvi-rectal flexure becomes readily opened out, since there

is no longer a loaded loop to be forced into the pelvis, and at the same time the general systemic effects of the accumulation of fæces are overcome After the operation it is well to attach the fascia of the outer side of the posterior abdominal wall to the mesentery in imitation of Nature's " last kink " to prevent subsequent strain upon it The operation that has been done is to expose the pelvic colon through a left paramedian incision and, having estimated the length of bowel to be removed, to resect it between clamps, placing the clamps obliquely, sloping from the mesenteric border away from each other in order to provide a wider surface for the junction

An end-to-end union is then made and the hole in the mesentery is repaired A Lane's colectomy tube, which is a large œsophageal tube with terminal and lateral eyes, is passed up the rectum by an assistant and is manipulated by the operator through the junction until its end is well up in the descending colon The tube is fixed by a stitch at the anus and, by preventing tension at the suture line for the first five or six days, adds very greatly to the safety of the operation If there is no development of the " last kink," a broad strip of fascia may be attached to the outer side of the mesentery proximal to the bowel to support it

There appears to be no tendency to stricture after this operation, even in young children, and in one child X rays taken three years after operation showed no sign of the anastomosis

Four Cases Related

CASE 1 —F S W , female, aged 7½, was seen on March 11th, 1921, with a history of continuous medical treatment under many physicians for the previous four years for " abdominal attacks " On inquiry it appeared that she was always constipated, but that the constipation was much more obstinate at times During these exacerbations she had pyrexia and headache and suffered from severe attacks of urticaria and asthma On three occasions she had had bleeding from the bowel The stools are foul, frothy, and undigested between the attacks, and after them are very hard During the attacks enemata are often without result, and the child states that she feels " something move inside " when she is at last able to have an evacuation

X ray examination by Dr N Mutch showed the cæcum, ascending, transverse, and descending colons to be normal, the pelvic colon was very dilated and elongated, forming a loop reaching well above the umbilicus There was a controlling appendix. On March 30th the appendix was removed and the redundant pelvic colon was resected, a tube being passed up through the anastomosis and left in for five days Copious liquid paraffin was given to keep the motion fluid The child left the nursing home on the twenty-first day with her bowels acting daily without purges

Dr Greenwood, of Ripon, who is now her doctor, has kindly allowed me to quote his letter —" The child has only occasionally complained of a transient pain in the umbilical region, relieved by a hot-water bottle or a dose of paraffin. She has a daily action of the bowels without any difficulty, taking liquid paraffin if there is any tendency to constipation, which seldom occurs She has no pyrexia, urticaria, or asthma, and is normal in weight and size. Mentally she is alert and normal, though somewhat childish for her age Her headmistress says that her age is mentally 11 (actual age 12¼) "

CASE 2 —P K , male, aged 7, seen in November, 1922, with Dr L. Mandel, under whose care he had been for some time He complained of pains in the stomach, legs and feet, and constipation, which was more severe than usual at times and was associated with considerable pyrexia and with attacks of urticaria, especially of the face He had previously been in one hospital with a diagnosis of ? Hirschsprung's disease, ? diverticulitis , at another hospital it was suggested that he might have a serous exudate into his bowel, in association with the urticaria, giving symptoms of intestinal obstruction He was very backward for his age and undergrown Dr Mandel treated him medically for eighteen months with repeated enemata and wash-outs of various kinds without improvement He was given paraffin, phenolphthalein and numerous purgatives, and a course of thyroid and pituitary extracts with no result X ray examination showed some delay in emptying the cæcum and marked elongation of the pelvic colon

All other measures having failed, it was decided after consultation to explore the abdomen The pelvic colon was found extremely long and thickened, and the redundant portion was excised with end to-end union A tube was passed up the rectum and through the anastomosis Recovery was uneventful The patient has had no further attacks of pyrexia and urticaria and usually his bowels are opened daily with a small dose of liquid paraffin About one year after operation he had one attack of constipation, but without pyrexia, which yielded to enemata given daily for a few days Otherwise he has remained perfectly well, and mentally and physically he is now a normal child for his age

The urticaria, asthma, and pyrexia in the first case, and the urticaria and pyrexia in the second would appear to be anaphylactic phenomena associated with the retention of fæces, and cleared up with remarkable rapidity after excision of the long pelvic colon and the abolition of the consequent stagnation of intestinal contents

CASE 3 —E B , female, aged 39, a nurse, was under the care of Dr N Mutch, and gave the following history Two years previously she had had an attack of acute obstruction, which was relieved without operation A year later she had severe attacks of abdominal pain with vomiting and the passage of blood and mucus per rectum. She also had great abdominal distension after taking any solid food She was operated on for " adhesions " in the spring of 1923 This improved her for a few months, after which her symptoms returned On admission she had continual aching pain in the abdomen with severe attacks at times She passed very little blood and an occasional mucus cast Her bowels had not acted without enemata for some months. Tenderness in the abdomen was most marked in the left iliac fossa X ray examination showed the pelvic colon to be very much elongated and thrown into a large loop While in hospital it was found impossible to discontinue the daily wash-outs without pain and distension following She passed casts while in hospital of from 1 to 3 feet in length

On June 26th, 1924, the abdomen was opened through a left paramedian incision, and the pelvic colon was found to be greatly elongated About 8 inches of redundant bowel was removed and an end-to-end anastomosis was made A tube was passed up the rectum through the junction.

She left hospital in a month free from pain and with the bowels acting normally Early in 1925 this patient had acute abdominal pain in the region of the incision and was re-operated on, adhesions to the scar being freed This relieved her at once, and since then she has remained well with the bowels acting normally

CASE 4 —H M R , male, aged 38, was admitted with abdominal pain Ten years ago he had a first attack of severe constipation, associated with abdominal pain, which was worse after food, and vomiting This condition recurred at intervals with intervals of freedom from symptoms Nine months ago he began to have severe colicky pains limited to the left iliac fossa and associated with complete constipation This type of trouble has been occurring at intervals ever since There has been no hæmatemesis or melæna He has lost 6 lb in weight in the last nine months X ray examination with a barium enema showed marked elongation of the pelvic colon, but no evidence of dilatation or obstruction

The abdomen was explored on Jan. 29th, 1926 the possibility of malignant disease of the colon being seriously entertained There was no growth, and no evidence of any gastric or duodenal ulcer The pelvic colon was much elongated, and the redundant portion, 10 inches, was removed with subsequent end-to-end anastomosis A tube was passed up the rectum through the anastomosis The patient left hospital on the eighteenth day, with the bowels acting normally and quite free from pain, and he has remained so since

Conclusions

Elongation of the pelvic colon would appear to be the determining factor of a group of somewhat severe symptoms in certain cases In the two children (Cases 1 and 2) the picture in each case is sufficiently similar to suggest a definite syndrome, the association of constipation occurring in attacks and accompanied by pyrexia, with urticaria and other anaphylactic phenomena, being very striking X ray evidence of elongation of the pelvic colon in such cases should bring the question of operation under consideration, since in both these cases prolonged medical treatment in expert hands had completely failed

Resection of the redundant pelvic colon does not appear to be associated with any considerable risk, provided a large tube is passed through the anastomosis and left in place for five days

The results of this operation in the four cases in which it has so far been performed have been satisfactory

⁂ Since the above was written the operation has been performed in a further adult case with satisfactory results

OBSERVATIONS ON CLIMATIC BUBO.

By H M HANSCHELL, D S C, L R C P, M R C S, D T M & Hy Camb,
HON MED SUPT AND M O IN CHARGE V D CLINIC, SEAMEN'S HOSPITAL, ROYAL ALBERT DOCK, LONDON

Among the seafarers of every nationality, race, religion, and colour who seek treatment at the Seamen's Hospital, "climatic bubo" is not a very rare complaint This note embodies the writer's observation of the condition in the West Indies and tropical Africa, and in patients at the hospital since January, 1919 The disease has not yet been reported in women

Diagnosis

Diagnosis depends on —

1 Inguinal adenitis and periadenitis

2 Absence of known more or less common lesions about the genital and anal area, such as primary syphilitic and chancroid ulcers, purulent balanitis, pediculosis, scabies, gonorrhœa, herpes genitalis, granuloma pudendi, and filariasis It must be remembered that inguinal adenitis may follow on chancroid ulcers, or a primary syphiloma, several weeks after these latter have healed, the blood should therefore be tested for Wassermann reaction A critical inspection of the genital apparatus and area, and the anal area, is necessary In two cases of climatic bubo where infection had apparently been acquired in coitus, respectively three and four weeks previously, I observed, besides some subacute balanitis, a few pin-head size shallow ulcers in the post-coronal sulcus of the glans penis These had healed completely 24 hours after swabbing with methylated (90 per cent) spirit

3 *Fever* —This may be absent when the case is first seen , it may develop later, or a history of past fever may be obtainable In all my cases it has been present at some stage of the disease Quite a small degree of adenitis and periadenitis, with no reddening of skin, may be accompanied by protracted irregular fever, though the temperature rarely reaches 103° F

4 A *history* indicating that the condition has developed after coitus in tropics or sub-tropics

One of my patients was a European seafarer, aged 17 years, with climatic bubo Although he had voyaged East, he denied any coitus at all It is possible, and not unlikely, that he spoke truth Climatic bubo, like the other venereal diseases, may possibly be acquired otherwise than in copula Nor, also, is the disease exclusively tropical Another patient, with fever and inguinal adenitis and periadenitis, absence of scars or lesions other than a mild patchy balanitis, and with a negative blood W R , denied any coitus during the previous 18 months except for one five weeks previously in Marseilles, which city marked his nearest and only approach to the tropics Still another patient, in whom climatic bubo was diagnosed on the grounds given above, had not been out of England at all The disease is climatic in the sense of being far more common in warm climates, and the designation "climatic" makes so socially convenient a cover for venereal bubo that it is likely to be retained and even extended It has already replaced "pestis minor"

Circumcision —I have not yet observed the disease in the circumcised The literature on the subject is silent on this point Among the patients attending the V D clinic of the Seamen's Hospital are many Indian "lascars" They are all Mahommedan and circumcised, with a genital area clean shaven They show their due proportion of inguinal buboes following chancroids or scabies of the genital area None has yet been found with climatic bubo In contrast, climatic bubo has been seen not rarely in the prepuce-bearing European, Chinaman, and negro, and in the uncircumcised Christian Indian, who provides a very small quota among the Indian seafarers treated at the hospital French observers in North Africa report the condition as one peculiar to the European Presumably the indigenous population is Mahommedan and Jew, and therefore circumcised

Organisms —I have detected no organisms by microscopic examination in the juice aspirated from unincised or unbroken inguinal glands, nor in sections of these glands have I found any organisms or any constant histological differences distinguishing the morbid changes from those seen in the inflamed glands resulting from scabies of the genital area, or ulcus molle

Treatment

In all cases the patient should be put to bed, whether fever be present or not Incision of the lesion leads inevitably to secondary infection with pyogenic organisms, to more incisions, and a great prolongation of the illness and incapacity If glands are excised, the large gape left in the groin becomes secondarily infected, and takes many weeks to heal

It is usually found that all the glands (not only the superficial group) are affected and thorough surgery therefore tries to extirpate them all One possible, and undesirable, result of this is shown by the following experience I had myself practised incision and excision until January, 1919, when I was shown by Dr G C Low a male European with elephantiasis of penis and one leg, and a splendid scar in each groin The elephantiasis had gradually developed during three years following surgical operation for climatic buboes in both groins At that time I had under my care a case of gonococcal urethritis and arthritis, with tender inguinal adenitis Intravenous injection of killed typhoid bacilli (in this case for the arthritis) had been followed by rapid disappearance of the inguinal adenitis

With this last case, and the picture of elephantiasis, fresh in mind, when a case of climatic bubo came under my care a few days later it was treated by intravenous injection of killed typhoid bacilli with the prompt vanishing of fever and quick decrease of the inguinal adenitis Since that date I have used this treatment in all cases of climatic bubo (and in many cases of ulcus molle buboes) with unfailing good results After the patient has been put to bed the glans penis and preputial sac should be thoroughly swabbed with methylated (90 per cent) spirit One such cleansing is sufficient to cure the mild degree of balanitis I have always found to be present Some of the cases have already suffered incision of the inguinal nodes or these have ruptured through the skin In consequence, secondary pyogenic infection has occurred All undermined overhanging inflamed skin should be cut away flush with the surrounding skin under local anæsthesia, and wet eusol dressings applied In these cases also, suppurating tracks debouching on to the surface should be laid open freely, the skin over them cut away, and wet eusol dressings applied No glands need ever be incised or excised If the skin be intact and fluctuation denote presence of pus in probable quantity of one drachm or more, *sterile* aspiration may be carried out—the puncture being sterilely sealed after evacuation If necessary, aspiration is repeated Where pus is suspected and rupture through the skin appears possible, the whole area should be sterilised with tincture of iodine and covered with sterile gauze No other surgical procedure is necessary If no pus be detected, the groins are covered with sterile gauze, over which thermogene wool is lightly bandaged The patient is then given an intravenous injection of killed typhoid bacilli, or a mixture of killed typhoid, paratyphoid A and B, bacilli, whether fever be present or no It has proved safe and effective to begin with 100 million bacilli This dose is followed in one or two hours' time by a rigor and rise of temperature to, it may be, 104° F Where fever is already present there is a rise of not more than 1½ to 2 degrees In a few hours the temperature falls to normal or below, with sweating In many cases this ends the illness There is no return of fever and the lesions in the groins rapidly subside If the patient be allowed up too soon there may be increase again of adenitis But it is rare for it to be necessary to keep the patient in bed longer than 14 days In some cases, however, the injection may have to be repeated in four or five days' time, and even a third time, with increasing doses, 150 million and 300 million I have not yet seen a case require more than three injections This treatment has converted what was very often a long, painful incapacitating illness, troublesome to the medical attendant, into a comparatively simple illness of one to three weeks' duration

My own experience has been entirely confirmed by the subsequent experience of Dr G C Low and Dr P H Manson-Bahr at the Hospital for Tropical Diseases in London

THE INTELLIGENCE OF CRIMINALS

By H A GRIERSON, M B, B S Lond,
AND
C H L RIXON, M D, M R C S, L R C P, D P M,
MEDICAL OFFICERS, H.M PRISON, BRIXTON

Observations on the intelligence of criminals have been made from time to time in various countries, but as far as the writers are aware no statistical information on the subject has hitherto been collected in this country The medical officers of English prisons make mental examinations of a large number of prisoners every year, but it must be remembered that in the vast majority of those cases the examination is made because there is some ground for suspecting that the prisoner is mentally abnormal Indeed, several hundred prisoners are remanded to this prison every year from the police courts of the metropolis solely in order that such an examination may be made before trial Other observers have given valuable statistics concerning the insane and mentally deficient who, at remand prisons, are thus constantly being weeded out before trial These records, however, give no information concerning those who are not thus eliminated, and it is in the endeavour to estimate the intelligence of those who arouse no suspicion as to their mental equipment—i e, the ordinary prisoner —that this study has been undertaken

For this purpose we have estimated the intelligence of 200 male prisoners, concerning each of whom we have also obtained information upon a number of other matters Since some method of selecting the subjects was necessary, the plan was adopted of taking the owner of the bottom name on each page of the Reception Register, in which the name of every man is entered at the time of his reception into prison It was thought advisable to exclude from the investigation prisoners committed for contempt of court, as these can hardly be considered in the same class as criminals It was foreseen that difficulty might arise from the inclusion of elderly prisoners, since the estimation of their intelligence is complicated by premature senile changes, which are apt to occur somewhat earlier in the class from which the majority of prisoners are recruited than it is in the higher social strata The effects of alcoholism and syphilis are also liable to upset calculations For these reasons it was thought wise not to include prisoners over 35 years of age If, therefore, the bottom name on any page of the Reception Register was that of a prisoner who had been committed for contempt of court, or was over 35 years of age, or had been remanded for mental examination the name above was taken

From each one of the prisoners thus selected a number of particulars were obtained, and his intelligence was then estimated by the Terman scale

The average mental age of the 200 prisoners was exactly 14 years, the individual mental ages being spread over a fairly wide range At the lowest end of the scale was a prisoner, charged with a trifling offence whose mental age was only 5–6 years He was actually 32 years old according to his own statements, but these were quite unreliable, and he had no relatives or friends who could give information about him He gave a history of having reached Standard II at school when 14 years old He made a precarious living by buying and selling small quantities of flowers, and his condition although doubtless congenital, had probably been aggravated by privation, as he was seldom able to afford accommodation in lodging-houses or a sufficiency of food He was extremely thin, and weighed only 7½ stone Although this prisoner was not remanded for the purpose of mental examination it was obviously right to inform the court of his condition This was done, and upon his reappearance there he was certified under the Mental Deficiency Act

At the other end of the scale were four prisoners, each of whom had a mental age of 19½ years—the highest that can be scored on the Terman scale—and they were plainly men of high mental ability. One, charged with burglary, was acquitted, but, as he had already been convicted of burglary on two previous occasions, his predilections were evidently similar to those of the other three, who were severally convicted of stealing machinery, of breaking into a church and stealing, and of being a suspected person Between these extremes all gradations of intelligence were found

Of the 200 prisoners examined, 181 were convicted One was found to be insane, and upon his reappearance at court was accordingly discharged to the Poor-law infirmary; one, as mentioned above, was found to be mentally deficient, and was certified as such; and 17 were acquitted The fact of acquittal must not, however, be regarded as evidence of a blameless past, for of the 17 so dealt with eight shared between them no less than 29 former convictions, so that these may fairly be considered to represent a similar class of persons to the 181 who were sentenced

Average mental ages associated with the various kinds of crime		Incidence of the different kinds of crime in 200 cases
Crimes	Years and months	
Fraud False pretences Forgery	15/2	17
Breaking and entering Burglary	14/5	32
Receiving Stealing	14/1	93
Crimes of violence	14	17
Suspected persons	13/10	22
Rape and sexual offences	12/4	8
Miscellaneous	13/3	11

The numbers examined are too small to warrant any hard-and-fast conclusions, but it is interesting to observe the relatively high intelligence displayed by the fraud and forgery group

The examination of these cases has again illustrated two points which are familiar to all who make frequent use of mental tests The first of these is that the standard of scholastic attainment is worthless as a guide to intelligence Thus, a youth charged with stealing jewellery had only reached Standard III. at school, but his mental age was $14\,^{5}/_{12}$ years Another, charged with rape, who had been in Standard ex-VII, had a mental age of 12 Both were subsequently convicted

The second point is the close correlation between the estimation of the intelligence by the vocabulary test alone with that obtained by using the entire series of tests The average mental age of the whole series measured by either of the methods, is exactly 14

Probably the most interesting figure which emerges from this study is the average mental age of 14 years No statistics are available, as far as we are aware, of the average mental age of the population as a whole: it would probably prove to be no higher than this, and many competent observers think it would be lower

The view that a man who takes to crime is, by that fact to be adjudged intellectually inferior to the righteous receives no support from these figures On the contrary they confirm the view generally held by those who have had experience of the criminal, that his intelligence is in no way below that of the "man in the street" He is "the man in the street"

This paper is published by permission of H M Prison Commissioners but it must not be taken as necessarily representing their views

Clinical and Laboratory Notes.

CARCINOMA CUTIS

MULTIPLE SKIN CANCERS OF OCCUPATIONAL ORIGIN

BY W J O'DONOVAN, M D, M R C P LOND,
ASSISTANT PHYSICIAN, SKIN DEPARTMENT, LONDON HOSPITAL

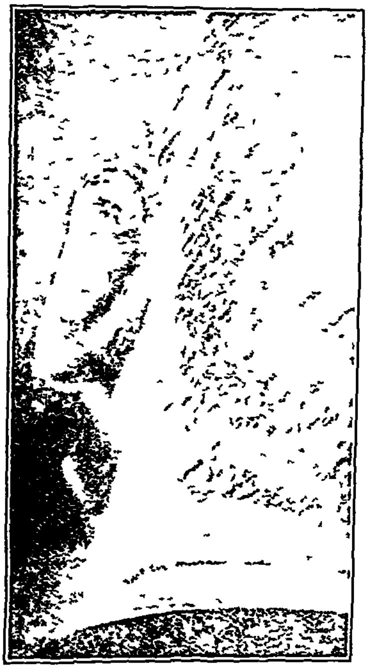
THE patient who is the subject of this report first attended the London Hospital in 1918 and has been under continuous observation since that date

History of the Case

The patient is now (1926) aged 55 He states that he has worked as a gunsmith for 30 years, and throughout this time he has always done the same class of work—i e, examining the component parts of old and rusty rifles and reconditioning them and in so doing has handled a vice, files, scrapers, and gauges Iron dust and rust is scattered on to his hands, face, and neck, in his work his clothes become oily all over, even to his shirt The chief oils used are Rangoon oil, paraffin oil, and some vaseline, but mostly the first From time to time he has suggested that his trouble might be due to this work, but has no knowledge of any fellow employee similarly affected

In 1914 a particle of steel entered his right eye, and it has been blind since He was treated for this at Moorfields and states that a small tumour near the eye was excised at this time In 1918 a "pimple" appeared at the end of his nose, and he was admitted for this into the London Hospital under Mr Souttar About this time he noticed lumps appearing on his skin, at first on his right forearm, then on his right leg then the left arm, and lastly both ears became implicated

FIG 1



"Oil" carcinoma of ear

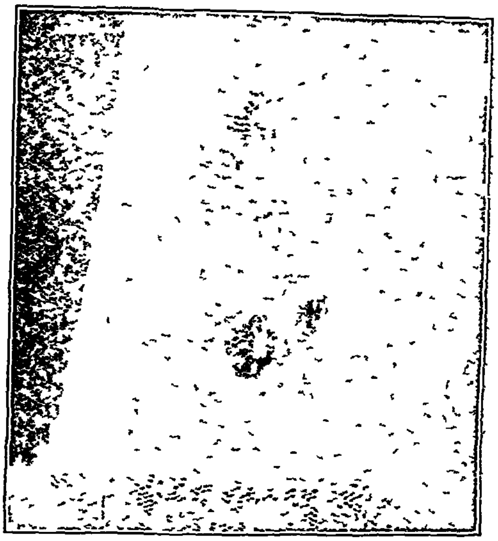
In May, 1923, he was referred to Dr J H Sequeira with a large ulcerated bulbous painful swelling on the tip of his nose The Wassermann was negative, a portion of the growth was removed for microscopical examination, and the pathological report upon it on June 19th, 1923, was "The tumour is a growth of squamous and horny epithelium, the bulk of the epithelial processes having a central cavity lined or filled with horn and so resembling hair follicles The processes are usually well defined by a basal layer, and there is no definite histological evidence of malignancy The growth is, however, so luxuriant, passing deeper into the dermis than the limits of the excision, that it would be advisable to treat it as definitely carcinomatous"

On June 24th, 1923, the growth then being the size of half a crown, he was readmitted and the whole of the growth, with the anterior portion of the nose was removed by Mr Perry The pathological report after the operation was "squamous-celled and horny carcinoma of skin of nose" He was provided with an artificial nose Dec 19th, 1923

Condition on Readmission in 1925

The patient reattended the skin department March 5th, 1925, with multiple cutaneous nodules about 1 cm in diameter on both arms As he had been taking medicine for a chronic cough the possibility of an iodide eruption was first excluded In August, 1925, a new nodule was noted on the left thigh and by December, 1925, nodules had appeared on the left ear, forearm, leg, and groins A nodule excised on Feb 11th, 1926, was submitted to microscopical examination, and the report was "Focal acute purulent and subacute inflammation in squamous and horny carcinoma of skin of inner surface of left thigh" In April of this year a nodule was removed from the right forearm, and the pathological report was "Squamous and horny carcinoma"

FIG 2.



"Oil" carcinomatous ulcers on right leg

In all the patient is certain that 15 separate tumours have been removed from the neck, chin, cheek, thigh, nose, forearm, and chest respectively He is a blonde of medium height with no signs of visceral disease and at present no adenopathy On the left ear is an ulcerated tumour 2 cm in diameter with a raised rolled edge (Fig 1) There is a smaller similar infiltrated ulcer on the antihelix of the right ear There are two similar 2 cm neoplastic ulcers on the right leg (Fig 2) and one on the outer aspect of the left arm one on the right forearm, and three on the scrotum, two of which are pedunculated and one sessile There are many comedones in the skin behind both ears, the patient presents no general nor local pigmentary changes

Comment

Multiple squamous-celled cutaneous carcinomata are much rarer than are multiple rodent ulcers No similar case has been reported in London, nor has any such case been seen previously at the London Hospital. One would have much hesitation in ascribing to this disease an occupational origin were it not for a report[4] of the Departmental Committee appointed to consider evidence as to the occurrence of epitheliomatous ulceration among mule-spinners, published by the Home Office in February, 1926

I have published groups of cases of squamous-celled carcinomata due to other occupational hazards anthracine,[1] tar,[2] and arsenic,[3] in previous issues of the *British Journal of Dermatology and Syphilis* By analogy with these other proved and accepted cases of multiple industrial carcinomata there seems an inherent probability that this case had also an industrial external cause, but before issuing any certificate to this effect both Dr J H Sequeira and myself felt that this case should be shown before our colleagues at the Dermatological Section of the Royal Society of Medicine

In Dr S A Henry's report[4] credit is given to Mr. S R Wilson and Mr A H Southam[5] for calling attention to the occurrence of occupational carcinomata in cotton-mills The Committee were able to trace up to the date of their report 539 cases "The age-period at which the cotton spinners' disease appears to be specially liable to manifest itself reaches its maximum about 55" (The age of the present case) In cotton-spinners as in tar and arsenic workers, the disease does not usually occur until the person affected has been employed for a considerable time. Mineral oils are held responsible and "the average duration of employment for all cases was approximately 41 years." (The present patient has been employed for 27 years.) A wide distribution of growths was noted in mule-spinners as in this case. Dr. Alex. Scott has reported[7] many cases of industrial skin cancer amongst the employees in the Scottish shale oil industry. Other cases of scrotal carcinoma apparently due to work in oil have been reported by foreign writers—Derville and Guermonprez[8] and Ehrlich.[9] In cotton mule-spinners (as in the present case) oil reaches the clothing of the workers, more particularly in the region of the groins, and the report draws attention to the practice of placing oil waste or even an oil-can in the trousers pocket.

It seems proper, then, to report this case as a new industrial hazard due to oil handled outside a refinery and analogous to the cancers found in "mule-spinners," tar-workers, patent fuel manufacturers, paraffin-workers, chimney-sweeps, and arsenical dip manufacturers.

Summary.

1. A case is reported of multiple cutaneous skin carcinomata. 2. The scrotum, face, limbs, and chest are sites of incidence. 3. So far local excision has succeeded, but new growths are appearing. 4. The patient has been employed in contact with mineral oil for 27 years. 5. The nature of the tumours has been demonstrated microscopically four times. 6. Arguments are adduced to establish the occupational cause of this disease. 7. Epitheliomatous ulceration due to mineral oil contracted in a factory or workshop is a notifiable disease by a Home Office Order of Nov. 28th, 1919.

A CASE OF
ACUTE DILATATION OF THE STOMACH
WITH AORTIC SUCCUSSION HEARD AT A DISTANCE OF TWELVE FEET.

By N. W. SNELL, M.B., B.S., M.R.C.P. LOND.,

AND

L. H. SAVIN, M.R.C.S. ENG.,

ASSISTANT MEDICAL OFFICERS TO ST. MARYLEBONE HOSPITAL, W.

On account of the unusual feature of the symptom observed in the following case we have thought it well to record it.

to be enormously distended, reaching well below the umbilicus and far into both flanks. It appeared to contain gas and fluid; and deep palpation revealed that the succussion splashes were being caused by a forcibly pulsating aorta, every beat of which drove the stomach against the anterior abdominal wall. This impact was visible. Rolling the patient on to his side or prone immediately stopped the splashes; but they returned at once on turning him on his back. The patient was retching and vomiting slightly during examination, the vomit being black. His heart was normal in size, position, and rhythm, the pulse-rate being 100. The temperature was 97·2° F.; respirations 22 per minute. There were numerous moist sounds at the lung bases, but no dullness or bronchial breathing. The teeth were carious and gums septic. There was a reducible right inguinal hernia and per rectum no scybalous masses could be felt, although the bowels had not been opened for two days. Although urine had not been passed for a day, the bladder was not distended. Tetany was well marked in the patient, spasms being present in hands and feet. Chvostek's sign was marked, a slight tap with the patella hammer over the facial nerve bringing on active twitching of the facial muscles. Trousseau's sign was present, compression of the forearm accentuating the typical "accoucheur's hand." We had no electrical apparatus handy for Erb's sign.

A diagnosis was made of acute dilatation of the stomach with aortic succussion and tetany. We were very interested in the acoustics of the condition, for though the stomach in these cases always contains gas and liquid, rhythmic loud succussion has apparently been reported only by Lennhardt in 1911. We do not think the loudness of the noise was due merely to excess of gas in the stomach relative to fluid. On first passing the stomach-tube we collected the gas evolved in a jar previously inverted in a basin of water. Only 5 oz. of gas were obtained in a large quantity of vomit. This gas did not burn but supported the combustion of a match.

We treated our patient on the classical lines suggested by Schnitzler in 1895 and independently by Box and Wallace in 1901. The man was put on his face with a pillow under his loins and chest, and the foot of the bed on blocks, thus endeavouring to relieve any obstructive pressure on the duodenum by the stomach or the superior mesenteric vessels. Hilton Fagge, when first describing the disease in 1873, remarked that after the relief of the stomach-tube his patient turned on one side of his own accord. Postural treatment instead of operative (Dorlin, 1918) has reduced the mortality of the disease from 72 to 7 per cent. Secondary lines of treatment adopted were rectal salines to make good the loss of fluid, stomach lavage, and two doses of 1 c.cm. of pituitrin.

By the next morning (Jan. 17th) the patient was much relieved, and by the evening tetany and distension had disappeared. The bowels were open. Urine showed a trace of albumin and the urea-coefficient was 1·7 per cent.

On Jan. 29th X ray examination showed a stomach in normal position, moderately active upon the meal. There was some definite delay in emptying at five and seven hours, and in the latter picture stomach residue was well defined. There was no proper duodenal picture throughout. This suggested the possibility of a pyloric ulcer. There was no occult blood in the fæces.

The patient made an uneventful recovery and was discharged on March 2nd, being instructed to report at intervals, especially if there should be any recrudescence of gastric symptoms.

Clinical and Laboratory Notes.

CARCINOMA CUTIS

MULTIPLE SKIN CANCERS OF OCCUPATIONAL ORIGIN

BY W J O'DONOVAN, M D , M R C P LOND ,
ASSISTANT PHYSICIAN, SKIN DEPARTMENT, LONDON HOSPITAL

THE patient who is the subject of this report first attended the London Hospital in 1918, and has been under continuous observation since that date

History of the Case

The patient is now (1926) aged 55 He states that he has worked as a gunsmith for 30 years, and throughout this time he has always done the same class of work—i e , examining the component parts of old and rusty rifles and reconditioning them , and in so doing has handled a vice, files, scrapers, and gauges Iron dust and rust is scattered on to his hands, face, and neck , in his work his clothes become oily all over, even to his shirt The chief oils used are Rangoon oil, paraffin oil, and some vaseline, but mostly the first From time to time he has suggested that his trouble might be due to this work, but has no knowledge of any fellow employee similarly affected

Comment

Multiple squamous-celled cutaneous carcinomata are much rarer than are multiple rodent ulcers No similar case has been reported in London, nor has any such case been seen previously at the London Hospital. One would have much hesitation in ascribing to this disease an occupational origin were it not for a report[1] of the Departmental Committee appointed to consider evidence as to the occurrence of epitheliomatous ulceration among mule-spinners, published by the Home Office in February, 1926

I have published groups of cases of squamous-celled carcinomata due to other occupational hazards anthracine[1] tar,[2] and arsenic,[3] in previous issues of the *British Journal of Dermatology and Syphilis* By analogy with these other proved and accepted cases of multiple industrial carcinomata there seems an inherent probability that this case had also an industrial external cause, but before issuing any certificate to this effect both Dr J H Sequeira and myself felt that this case should be shown before our colleagues at the Dermatological Section of the Royal Society of Medicine

In Dr S A Henry's report[4] credit is given to Mr. S R Wilson and Mr A H Southam[5] for calling attention to the occurrence of occupational carcinomata in cotton-mills The Committee were able to trace up to the date of their report 539 cases " The age-period at which the cotton spinners' disease appears to be specially liable to manifest itself reaches its maximum about 55 " (The age of the present case) In cotton-spinners, as in tar and arsenic-workers, the disease does not usually occur un [illegible] son

Provided the transfusion was given according to the rule laid down no ill-results followed It was easy experimentally to bring about the death of an animal by transfusing rapidly or by rather slower transfusions, to produce reactions of every degree of severity Death was due to dilatation of the right heart or to pulmonary embolism

Dr E I SPRIGGS (Ruthin) gave some practical details of technique and referred to the advantage of using the sphygmomanometer bag instead of the tourniquet Except in very severe cases it was better not to cut down upon a vein, after dilatation had been produced with the bag the blood could be drawn off with a sharp needle and syringe Where citrated blood was used an induction bag should be employed to supplement the force of gravity If at any time during the transfusion there was clotting of the blood the experiment must be recommenced Dr Spriggs emphasised the importance of blood transfusion as a prophylactic measure against operative shock and also in cases of bowel hæmorrhage secondary hæmorrhage and pernicious anæmia In cases of serious injuries it had been invaluable in preventing subsequent sepsis as was shown during the war It was well to bear in mind that the donors might be suffering from syphilis, and the Wassermann reaction should be tested if this had not been done during the preceding year

Mr GEOFFREY KEYNES (London) said that the growth of blood transfusion as a therapeutic measure had been slow, but it was now recognised as an essential part of surgical treatment The branch of the British Red Cross Society known as the Blood Transfusion Service had done invaluable work in overcoming the difficulty of obtaining suitable donors In surgery transfusion had been chiefly used in gastric and duodenal cases, but many other conditions had also benefited Experience had shown that if transfusion was given purely with a view to replacing blood lost and discouraging further hæmorrhage as in acute ulcer, it should be done without delay Where operation was considered necessary the idea was to give one transfusion a few hours before operation and a second while the operation was actually proceeding

Dr W T. ROWE (Nottingham) reported some encouraging results in the treatment of infective endocarditis, pernicious anæmia, and purpura hæmorrhagica The introduction of cool blood was one of the causes of rigor The patient should be kept thoroughly warm both before and after blood transfusion

Prof. E A. GRAHAM (St Louis, U.S A.) said that blood transfusion was overdone in anæmia, but he was very optimistic about its use in well-selected cases In severe burns transfusion might be useful

Dr ROBERT PLATT (Sheffield) spoke of the good results he had obtained when using defibrinated blood He considered that the method introduced by Colebrook and Storer[1] was just as easy as the citrated method In septic cases he had had fair results and inclined towards an optimistic view.

SIR HUMPHRY ROLLESTON in his reply said that Prof. Cruchet had clearly shown the necessity for slow transfusion Possibly desensitisation took place during transfusion

FRIDAY, JULY 23RD

The third session of this Section was devoted to a discussion on

The Nature of Malignant Neoplasia and the Treatment of this Disease with Lead

Dr J G ADAMI (Liverpool) read a paper by Prof Blair Bell (Liverpool), who was unable to be present owing to illness It was, Prof Bell considered, more essential to discover the nature of the cancerous process itself—the character of the change from normal growth to cancerous development—than to discover the so-called causes which were really predisposing factors There were many extrinsic and intrinsic factors which could produce the pre-cancerous condition in, or in relation to, the cells concerned These included radiation of various kinds, heat, trauma, infection, toxæmias, and senescence, all of which reduced the vitality of the cell It seemed probable that the metabolic disturbance leading to the change might be oxygen starvation The ancestral type to which the cell sought to return in the reversionary process was that of the chorionic epithelium, which had the power to invade and erode blood-vessels in its search for nutriment It might be expected that cells of the chorionic epithelium would resemble malignant cells in structure, function, and chemical composition, and in toxicological affinities The investigation of this working hypothesis undertaken at Liverpool had presented a formidable array of problems In seeking for a therapeutic agent lead was chosen because of its action on chorionic epithelium, but to have found that chorionic epithelium and cancer cells were similar in nature and that lead was specifically toxic to both was not enough The results must be improved and rendered consistent, and patients must be protected against the harmful effects of lead poisoning

Prof W C McC LEWIS (Liverpool) said that cancerous tissues, freshly removed from the body, had a higher electrical conductivity than normal tissues under the same conditions and that this conductivity was higher in peripheral portions of a growth than in the central non-growing portion The increased conductivity necessarily meant that there was increased permeability of membranes or septa in the cells to electrically charged atoms or ions, and these electrical measurements suggested that increased permeability was a definite feature of malignant disease In malignant growths the ratio of lecithin to cholesterol was excessive A similar ratio was found in the chorionic villi and such results were strong evidence of a fundamental similarity between the two types of structure No difference in the pH of the blood could be detected in malignancy, but any abnormal value would be masked by the buffer action of the blood and by the power of the liver and muscles to take up lactic acid In the Rous sarcoma the blood which had passed through the tumour was found to contain more lactic acid than was normal, which pointed to the production of acid in the growing part of the tumour. In experimental tar cancer in rabbits certain observers found the pH of the plasma to be considerably lowered in the precancerous stage (from an average value of 7 31 to an average of 7 17) The blood of cancer patients usually exhibited anti-tryptic activity. Excessive glucolysis was shown by Warburg to be characteristic of malignant growth, but the fundamental problem of its nature and origin remained unsolved The clinical value of lead was possibly a result of its causing the cessation of certain chemical processes due to enzymes, upon which the activity of the cell depended

Action of Lead

Prof W J DILLING (Liverpool) said that his experiments on germination of frogs' eggs and on growth of tadpoles had shown that resistance to the poisonous effects of lead was directly related to the age of the tadpole, and that extremely weak solutions of lead acetate (1 in 100,000) retarded growth It had been deduced (1) that lead is more toxic to growing than to embryonic tissues, (2) that its adverse action is toxic, and may be responsible for temporary sterility and early abortion, (3) that in non-lethal amounts this retarding effect is inversely proportional to the age of the animal, and (4) that it inhibits growth Experiments were made on the isolated intestine of a guinea-pig and rabbit to test the action of a partly ionic and partly colloidal preparation of lead Lead produced relaxation and inhibition of peristalsis without interfering with the vagus mechanism of the muscle It was suggested that colic might be prevented by linking up a phosphorus ion with lead. Prof Dilling referred to a lead preparation which was going to be released and which might prove both useful and safe

Prof. CARTER WOOD (Crocker Institute for Cancer Research, Columbia) described the results of his

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT NOTTINGHAM.

(Continued from p 237)

SECTION OF MEDICINE

THURSDAY, JULY 22ND

AT the second session of this Section, Dr F H JACOB, the President, being in the chair, a discussion on

Blood Transfusion in the Treatment of Disease

was opened by Sir HUMPHRY ROLLESTON (Cambridge), who gave a brief account of the history of transfusion Like most remedies powerful for good, its employment, he said, might be attended by unpleasant or serious results, and this, combined with difficulties in technique, had led to its adoption often being delayed until the patient was beyond curative measures, or even in extremis The period during which transfused red cells persisted in the recipient's blood varied, according to Ashby's differential agglutination method, *between 59 and 113 days It was shorter in hæmolytic* and toxic states, and longer in traumatic anæmia Post-transfusion reactions had been reduced from 34 per cent to 4 per cent by improvement in technique, but according to Kordenat and Smithies all transfusions were followed by a rise of temperature within three hours Some reactions, due to gross incompatibility, to air embolism, and pulmonary œdema should be obviated by care in typing the blood of donors and patients and in technique It was, however, difficult to separate slight degrees of incompatibility in vitro, as they were often due to minor agglutinations. This was especially true in severe chronic anæmia, and there was evidence to show that in addition to the four recognised blood groups there were abnormal groups in pernicious anæmia, chronic hæmolytic jaundice, and malignant disease Reactions were more likely to occur after large transfusions than after small ones, and also after repeated injections, when they might be due to anaphylactic shock, the patient having become sensitised It might be wise, therefore, to repeat the blood tests before each transfusion Kordenat and Smithies classified reactions as follows (1) Acute and fulminant response due to agglutination and hæmolysis, coming on immediately This should be prevented by careful preliminary typing of the donor's and recipient's blood (2) Delayed and proteolytic response coming on from 1 to 12 hours after transfusion and ascribed to bacteriolysis and to protein cleavage of damaged tissues at an infective focus and not to hæmolysis (3) Systemic or constitutional reactions which like the last group, were not hæmolytic, as there was no evidence of blood destruction No satisfactory explanation of these reactions was forthcoming, and it was possible that they might be due to different factors in each case

There were four groups of cases, said Sir Humphry Rolleston, in which blood transfusion might be expected to do good According to Keynes's classification they were as follows (1) acute hæmorrhage and anæmia and associated shock, (2) chronic anæmia—to tide a patient over an operation and prolong life, or in the hope of cure, as in Addisonian anæmia, (3) hæmorrhagic diseases, and (4) general toxæmia, bacterial or chemical He concluded his address with a detailed account of the effects of transfusion in each of these groups

Prof G L GULLAND (Edinburgh), giving his impressions of 40 years' experience of blood transfusion, referred to the reactions observed before the days of blood grouping He was struck, he said, by the luck he had had, for in only two cases had there been trouble, since the introduction of grouping he had been less fortunate In pernicious anæmia, which was due to a toxæmia, there was interference with the function of the bone-marrow, and the aim of therapeutics must be to stimulate its hyperplasia Megaloblasts were formed, and if the patient recovered sufficiently, then normoblasts began to be formed also In treating the disease the toxic processes must be exhausted and in the great majority of cases this should bring about a cure The object of transfusing blood must be to help the patient to recover himself There was always a chance that the necessary antibodies would be contained in the blood, and it was therefore better to use young patients as donors If one transfusion did not lead to a response a second would not In no case of acute leukæmia had transfusion affected the course of the disease In chronic leukæmia the only indication for blood transfusion was intractable hæmorrhage which would not yield to any other treatment In hæmophiliacs transfusion might be useful when teeth had to be removed Prof Gulland said that he had not yet made up his mind whether the treatment was efficacious in purpura hæmorrhagica, but some cases had improved and there had been no bad results

Prof RÉNÉ CRUCHET (Bordeaux) spoke on transfusion of blood from animal to man Following Harvey's discovery of the circulation of the blood, bold surgeons, such as Wren, Boyle, and Clarke, between 1656 and 1660 began the practice of injecting drugs into the veins of animals and even of men—so-called infusory surgery Thence arose transfusory surgery—i e, transfusion of blood between animals, first of the same and then of different species In England in 1667 Edmund King and Thomas Cox transfused successfully from calf to sheep, but it was the Frenchman Denys, of Montpellier, who first applied the method to man, and in 1667 transfused four subjects with the blood of lambs and calves Later transfusion fell into disrepute, and was not revived until 1860, when Dr Oré, of Bordeaux, began his classical studies on the subject He transfused from animals to man, but his most favourable statistics showed a 16 per cent mortality, and severe reactions were frequent Meanwhile improvements in surgery and technique encouraged the hope that a renewed investigation would prove fruitful, and in 1921 Prof Cruchet took up the work The first injections of sheep and horses' *blood into patients* were followed by rather severe reactions and one death, but the majority of patients were benefited Further experiments led to the conclusion *that bad technique* alone was responsible for accidents

The principle of transfusion for any substance, continued Prof Cruchet, was that the rate of flow into the vein must be inversely proportional to its viscosity It was of the utmost importance to transfuse exceedingly slowly, especially during the *first period* The first half cubic centimetre of blood should take a minute to pass into the vein After this the flow should be accelerated in arithmetical *progression* until a quarter of the whole *amount* to be transfused had been given The second period was then reached, and the flow was continued at a uniform *rate until the end* of the period, when *it slacked off* In the third period the flow was again accelerated and kept at full speed till the operation was over So long *as the law of the* rate of flow was *not* violated the compatibility or otherwise of the bloods was of no consequence, and accidents did not occur The danger of *agglutination* was much exaggerated, *for drugs* which had the power of agglutinating human blood were frequently injected into veins without ill-effect *Hæmolysis* was an independent phenomenon, and always occurred to a slight extent when animals' blood was transfused.

from cooperation with the neurologist X rays might show up the tumour if there were any calcareous matter present, a condition rarely seen in cerebral tumours they were occasionally useful in pituitary tumours and where an endothelioma had eroded the inner table of the skull He referred to the relation to trauma and thought that, while it was impossible to be absolutely certain, there did seem to be some relation between a severe head injury and the occasional development of a glioma

Mr H S Souttar (London) demonstrated an ingenious instrument for turning down large osteoplastic flaps He felt that the bone flaps should be replaced and little of the skull should be removed He turned down a large scalp flap and found that it did not interfere with the vitality of the bone He removed the bone under local anæsthesia The dura mater, he said, was insensitive.

Mr G Jefferson (Manchester) emphasised the difference between skull surgery and brain surgery The former was easy and largely a matter of technique, while the latter required in addition extensive training in diagnosis and pathology He felt that neurological surgery was not nearly as advanced as that of other regions, which he attributed to the prevailing idea that a diagnosis of cerebral tumour could be made only with difficulty, and that when this had been done apart from improvement in pressure symptoms surgery offered but little hope of relief and none of cure This however, was contrary to the experience of those who paid particular attention to this branch of surgery

Mr J P Ross (London) pointed out that it was important when operating to allow the fluid to escape slowly so that the pressure was gradually lowered, otherwise œdema of the brain was apt to follow Cerebral compression arising after the operation might be due to the onset of cerebral œdema or to hæmorrhage The former might be combated by the intravenous injection of 75 c cm of 15 per cent saline Otherwise it was necessary to re-operate and take away part of the bone The latter could be prevented by greater care in stopping the bleeding during the operation.

A discussion on the

Place of Gastro-enterostomy in Gastric and Duodenal Surgery

was opened by Mr H J. Paterson (London), who remarked that no other operation had done so much to lead to human happiness Its very success had led to its employment in unsuitable cases, and it was to this and to an imperfect technique that some of the bad after-results were due Permanent cures followed in 82 per cent of gastric ulcers and in over 90 per cent of duodenal ulcers This percentage would undoubtedly be higher had he not included the cases he could not trace among those regarded as not cured The results after anterior gastro-enterostomy were somewhat better than after the posterior method, as the alkaline pancreatic juice flowed more easily into the stomach and neutralised the acidity of the gastric juice, which was the most active factor in keeping up the ulceration It was the method he now practically always adopted The operation should never be done merely upon a clinical or X ray diagnosis It was essential that the ulcer should be seen and felt This operation did not cure the ulceration, but merely placed it under the best conditions for cure It was essential that the operation should be followed by prolonged and effective after-treatment In some cases owing to the condition of the home-life this could not be done, which was responsible for poor results There was great need for convalescent homes and after-care centres in this country Gastro-enterostomy should be done in perforated ulcers as convalescence was smoother and shorter. It should not be done if it were suspected that the ulcer were malignant He did not operate for hæmorrhage, as this was best treated by medical means

The advocates of partial gastrectomy urged that it was a more certain cure of the ulcer, that it prevented the later onset of cancer, and that jejunal ulcer did not follow The jejunal ulcer was due to hyperacidity and did not result after gastro enterostomy if proper after-treatment were carried out It was stated that 60 per cent of gastric ulcers became malignant This was not borne out by the clinical or pathological findings The long history obtained in gastric cancer was due not to preceding ulceration, but to intestinal stasis None claimed that gastro-enterostomy was a preventive against cancer, yet only 2 per cent of such cases were stated to die of cancer and if these were carefully investigated it would be found that the diagnosis was wrong and that the cancer arose in other parts The mortality after gastrectomy was as high as the combined mortality and the complications after gastro-enterostomy Time alone could show whether the end-results were better, but it should not be forgotten that some of the strongest advocates of gastrectomy to-day were equally strong in their advocacy of gastro-enterostomy some years ago

Prof Finsterer (Vienna) said that he no longer performed gastro-enterostomy as the results were not satisfactory The ulcer did not heal, jejunal ulcers occurred, and hæmorrhage and perforation were not unknown He did a gastrectomy in all cases of gastric ulcer unless complicated by a perforation, and a duodenectomy in duodenal ulcers unless the ulcer extended as far as the ampulla of Vater or unless the common bile-duct could not be separated from it. The mortality for gastrectomy was 1 per cent and for duodenectomy 2 per cent in 503 resections, which included 86 patients between 60 and 80 The operation should be followed by a light diet for three months, at the end of which time the patients were able to go on a full diet and to resume ordinary work, 98 per cent. were permanently cured Only one gastro-jejunal ulcer occurred in his cases It was important to remove sufficient of the stomach; the pylorus and at least two-thirds of the body should be removed He preferred the Billroth II method and avoided the Y-shaped anastomosis

Mr K. W Monsarrat (Liverpool) pointed out that when the ulcer was healed and merely a stenosis present, a perfect result followed gastro-enterostomy. When there was active ulceration the results were not so good He considered the position of the opening was of great importance and should be as low as possible Whenever possible he in addition excised a gastric ulcer and infolded a duodenal ulcer

Mr Charles Roberts (Manchester) stressed the importance of efficient after-treatment. It was not sufficient to give only verbal advice as this was often imperfectly understood and soon forgotten Printed instructions should be issued An alkaline bismuth mixture should be continued for at least six months. An anterior gastro-enterostomy was less favourable than a posterior as it predisposed to intestinal obstruction The appendix should always be removed He performed gastrectomy only in large gastric ulcers or in cases in which gastro-enterostomy was not successful.

Mr E Deanesly (Wolverhampton) felt that in the majority of gastric ulcers some form of resection was necessary, while in duodenal ulcer gastro-enterostomy led to a cure The bad results that followed the latter operation were due to contraction of the opening, which prevented rapid emptying of the stomach. This he considered was essential to the rapid healing of the ulcer To facilitate it he in some cases resorted to Finney's operation

Mr A. B Mitchell (Belfast) stated that while a gastro-enterostomy in suitable cases did good, he was doubtful if any other operation led to more suffering when carried out in unsuitable cases or with bad technique When hæmorrhage followed a gastro-enterostomy for duodenal ulcer the latter was often in the first part of the duodenum and fixed to the posterior wall If the duodenal branch of the gastro-duodenal artery were picked up and ligatured at the operation this hæmorrhage could be prevented When hæmorrhage followed gastro-enterostomy it came as often from the ulcer as from the anastomosis With the perforated ulcer he did a gastro-enterostomy if the investigation into the changes produced by lead on large transplantable rat tumours Intravenous injections of fresh preparations of the non-toxic mixture of lead were given, and after two or three days the tumour diminished in size and there was sometimes a little redness and œdema around it On section the tumours thus treated were found to be filled with blood, especially the sarcomas , the carcinomas were apt to shrink and did not show so much hæmorrhage In these advanced cases it had been found difficult to sterilise all the cells of the tumour, but occasionally cure was maintained On microscopical examination the capillaries of the capsule were seen to be distended with red blood corpuscles, which accounted for the pain sometimes present 48 hours after injection In the tumour itself thrombi were found partially organised, and round these thrombosed vessels there was softening In the liver, after small doses, there might be focal necrosis Prof Wood concluded that the first effect of the lead was a thrombosis The surrounding tissues then underwent change owing to the toxic action of the lead upon them The tumours were not cured in all cases, but these tumours in the rat were more malignant than in man Lead did exert a toxic influence on them, and cures had occurred

Prof. E. E Glynn (Liverpool) said that investigations would go on for at least another year The following conclusions had so far been reached (1) There was histological evidence that lead had damaged a very small percentage of the malignant neoplasms examined from patients It would not be expected that a large percentage would show damage, because only a comparatively small number of patients were clinically benefited by lead There was a greater tendency to necrosis, and sometimes to a slowing in the rate of growth so that the malignant cells had time to become more specialised , thus keratinisation and the formation of cell nests and goblet cells appeared to be more common (2) There was no damage to malignant growths which was histologically pathognomonic of lead It most probably acted by increasing the regressive changes which normally occurred to a greater or less degree in all malignant neoplasms. The tendency to thrombosis in carcinoma was no greater , thrombosis in sarcoma might be more common, but it was probably secondary. The absence, however, of any characteristic changes was no proof that lead had no action If an investigation were made into the effects of arsenic or mercury on chancres or gummata nothing histologically pathognomonic of these remedies would be found (3) The effect of lead upon a similar malignant growth varied very greatly, even when it was administered under apparently the same conditions This suggested that the patients' tissues or resistance, using the term in its widest sense, probably played a part in determining the success or failure of treatment, as they did in malaria treated with quinine and in syphilis treated with mercury.

Treatment with Lead

Dr L Cunningham (Liverpool) said that in treating cases of malignant disease with lead one of the greatest difficulties had been the selection of cases which presented a reasonable chance of being benefited and could at the same time withstand the toxic effects of the drug Some patients were unaffected by large doses , others were made very ill and might even die after a moderate dose Before undertaking treatment he carried out complete investigations on the blood and urine, and if necessary made liver function tests as well The administration of lead was usually accompanied by some reaction Toxic effects had been observed, not only in the blood and blood-forming organs, but also in the gastro-intestinal system, the kidneys, liver, and, to a lesser extent, the central nervous system He described these effects and outlined their treatment The preparation of lead was nearly always given intravenously, but ionisation was also used for superficial tumours The dosage varied with the particular case under treatment, and the investigators were not satisfied that the optimal dose had yet been discovered Latterly they had given four doses of 15 c cm of the 0 5 per cent preparation at intervals of 10 days After a month's rest a further course of smaller doses was given, until a total of 0 6 g of lead had been reached Out of 227 cases treated 50 had shown benefit The disease was believed to be cured in 41

Dr S Miller (Harrogate) said that so far 18 cases at Harrogate had been treated with lead No serious reaction had occurred, but one patient had vomited persistently for ten days On the whole during the last three months improvement had occurred The blood should be examined, for the occurrence of stippling was an indication of the effect the lead was having

Mr Frank Cook (London) described the satisfactory results he had had in what was considered a hopeless case Lead should not be used, he thought, unless the doctor was in touch with a body of men who were constantly practising with it

Dr Cunningham, replying, agreed that blood films should be taken during treatment, about every month , Leishman's stain could be used to show stippling At present it was unwise for a doctor to treat cases on his own ; he should be in touch with a clinic

SECTION OF SURGERY

Wednesday, July 21st

In the absence of Sir D'Arcy Power, owing to illness, Sir James Berry presided at the first two sessions of this Section On Wednesday a discussion on

Cerebral Tumours

was opened by Mr Percy Sargent (London), who began by pointing out that much of Sir Victor Horsley's work still held good to-day Horsley had all along condemned expectant treatment, for in cases of cerebral tumour the patient could look to the surgeon alone for relief Radiotherapy was very disappointing, though occasionally the employment of radium combined with operation in a glioma had seemed to modify the natural course of the case It was to-day possible to predict the exact site and the probable nature of the growth

Taking in succession the various types of tumour, Mr Sargent said that *gliomata* were of two kinds—those which are apparently encapsuled and may undergo cystic degeneration, and those which grow rapidly and infiltrate the surrounding tissues, though they never involve the membranes or the bone The prognosis was better when they affected the cerebellum *Endotheliomata* were innocent in nature and the most favourable of all the intracranial tumours for radical treatment They were easily enucleated, were attached to the overlying dura mater, but never invaded the brain The operative mortality was, however, high Of the *cerebello-pontine tumours* 90 per cent were neurofibromata They were often encapsuled and arose near the eighth nerve Deafness and noises in the head might be the only symptoms The corneal reflex was often diminished Intracranial pressure developed only late Their removal was often difficult as they lay so near the medulla, and interference of the blood-supply of the latter with its serious consequences might result from the operation. *Pituitary tumours* were of two types, those of the gland proper, which were usually adenomata, and those of the interpeduncular space It was the former which were most favourable for operation

Figures were quoted to show that the results of operation were not so deplorable as was often thought In a fair proportion, varying with the nature of the growth and the time of diagnosis, a permanent cure without any subsequent neurological defect followed Better results were to be obtained only by earlier diagnosis, and it was to be regretted that the signs of a tumour of the brain as commonly taught were headache, vomiting, and optic neuritis These were rather the signs of increased cerebral pressure There should be greater familiarity with the ophthalmoscope, but he felt that earlier diagnosis would be possible only

Mr E Deanesly (Wolverhampton) considered that the trouble lay in removing the glands and not the growth, for recurrence was rarely seen in the mouth It was only when the growth was extensive that he used diathermy In elderly people he did not remove the glands

Mr Stanford Cade (London) considered that the primary growth should be treated by the insertion of radium needles If the glands were operable they should be removed by block dissection, otherwise radium should be applied At the Curie Institute it was claimed that 25 per cent were alive at the end of five years

Mr W H Carson (London) read a paper on

Post-operative Treatment of Carcinoma of the Breast

During the operation he removed the minimum amount of skin to make certain of primary union, and the incision should be so designed that the scar was kept out of the axilla To prevent the shock which might develop three to four hours after the operation the patient was placed between blankets under a cradle heated with electrical lamps and was given one pint of saline containing 5 per cent. glucose immediately on returning to bed, and this was repeated in one hour Morphia was given if necessary. It was important to avoid hyper-extension of the arm during the operation as in two of his cases paralysis of the biceps followed though return of power took place He always drained with a tube in the axilla which was removed on the second day It was important to look out for accumulations of fluid that might take place below the clavicle and over the upper part of the rectus The bandage over the chest should not be too tight The arm should be kept at a right angle from the beginning and should be fastened to the bed The patient should be sat up after the first few hours. To prevent the scar becoming adherent to the chest wall the skin should be gently massaged each day.

Mr R E Kelly (Liverpool) considered that more skin should be taken away and that the flaps should be carefully cleaned as recurrences did not take place in the scar, but about one and a half inches away

Mr Garnett Wright (Manchester) emphasised the placing of the incision so that no band formed between the chest wall and the inner aspect of the upper arm He preferred a continuous suture for the skin, as it reduced the tension more than interrupted sutures He did not consider that placing the arm at a right angle was of much importance provided active and passive movements were carried out from the day after the operation

Mr Gordon Taylor stated that he had employed X ray irradiation in cases he had operated upon since the war He considered the results were worse than when it was not employed and he had now given it up Much of the bleeding during the operation came from the smaller vessels of the skin, and this could be prevented by employing the diathermy knife

Mr G Simpson considered that X ray irradiation was undoubtedly of value in after-treatment

Mr A B Mitchell (Belfast) read a paper on the

Treatment of Spiral Fractures

He pointed out that the difficulties in treatment were due to the sharp end of the upper fragment becoming firmly embedded in the muscles and to the tendency of the lower fragment to rotate If he could not produce accurate apposition by the end of a week he always operated By bringing both fragments out into the wound accurate apposition could be obtained This was maintained by wire wound round the ends, which did not pierce the bone and plates were unnecessary and might do much damage Kangaroo tendon and silk could not be tied sufficiently tightly to maintain the apposition

Friday July 23rd

This was a joint meeting with the Section of Anæsthetics, at which Dr Samuel Johnston (Toronto) presided, when a discussion on

Anæsthesia in Abdominal Surgery

was opened by Prof Hans Finsterer (Vienna) He stated that in major operations upon the abdomen he had given up anæsthetising by ether and chloroform as though there was no difficulty in obtaining relaxation, a fall in the blood pressure and much shock followed lung complications were common and serious changes in the heart liver, and kidneys were apt to supervene In acute abdominal affections they often gave rise to fatal hepatic insufficiency and in long abdominal operations he felt their use led to interference with the resisting power of the peritoneum and favoured the onset of peritonitis He therefore had fallen back upon some variety of regional anæsthesia Novocaine gave good results and 200 c cm. of ½ per cent solution might be used, but it was important to take into account the general condition of the patient and if there was marked cachexia or anæmia the strength should be ¼ per cent If the dose were adjusted to suit the patient s strength, pallor, restlessness, and air hunger were avoided. Tutocaine was coming into favour in Germany and could be used in strengths of 1/5 to 1/8 per cent. : it was more effective, and vomiting was rarer If the patient was very nervous he induced with ether, and this might be given in small amounts throughout the operation If however, the patient insisted upon general anæsthesia alone he now refused to operate He had been impressed with the nitrous-oxide-oxygen method of the Americans, which he should have preferred but this was too expensive to have any scope in Austria Ethylene and acetylene were too inflammable In operations upon the abdominal cavity it was necessary to anæsthetise the peritoneum of the posterior as well as the anterior abdominal wall. Injection of the mesentery alone combined with infiltration anæsthesia was of value only if there was no pulling upon the viscera He had given up spinal anæsthesia, as the fall in the blood pressure often led to severe collapse Paravertebral anæsthesia was of advantage when the operation was limited to one side of the abdomen, as in those upon the gall-bladder and resection of the colon He however now used chiefly splanchnic anæsthesia in which the splanchnic nerve trunks were injected. This could be done posteriorly by the method of Kappis or anteriorly by the method of Braun after opening the peritoneum. Kappis s method was somewhat more dangerous than that of Braun owing to the possibility of injecting the fluid into the veins or into the spinal cord ; it was, however, the method chiefly employed in England and America. With Braun s method 70 c.cm. of ½ per cent. novocaine were sufficient Care should be taken to displace the vena cava with the forefinger so that the injection was not made directly into it If it was impossible to separate the aorta and the cava the novocaine had better be injected into the mesentery. In 8 per cent. of cases the administration of ether was necessary, chiefly in cases where marked adhesions were present, but the amount needed was very small Should exploration of the whole of the abdominal cavity be necessary, temporary general anæsthesia would be necessary In operations upon the lower abdomen parasacral anæsthesia was not sufficient for removal of the rectum The injection of novocaine at the base of the meso-sigmoid from behind or on the anterior surface of the fifth lumbar vertebra after opening the peritoneum was needed As a result of regional anæsthesia lung complications he said had disappeared, shock was much less and he was prepared to operate upon patients whose condition a few years ago would have been regarded as hopeless. In addition perfect prolonged relaxation could be obtained Statistics of such severe operations as resection of the stomach or colon removal of the gall-bladder, &c., were given to show the marked improvement that had appeared in recent years since this method was introduced The results in patients of 60 to 80 were as satisfactory as those in younger ones

Dr C W Moots (Toledo Ohio) emphasised the following points : 1. The necessity for a complete clinical examination before the operation when the activity of all the vital organs should be investigated. A preliminary consultation between the surgeon and the anæsthetist should always be held 2 The blood shock was not too great and if there was not too much extravasation into the peritoneal cavity. It could be done more often with a perforated duodenal ulcer as owing to the associated spasm of the gastric sphincter there was less extravasation and less shock.

Sir **William Wheeler** (Dublin) felt that in operating in cases of ulcer two factors should be taken into account—the ability of the individual and the local condition present. Cancer did at times follow an ulcer, and he had come across three undoubted cases. When performing gastro-enterostomy he infolded the ulcer to prevent perforation and picked up the arteries to prevent bleeding.

Prof. H. A. **Bruce** (Toronto) pointed out that while gastrectomy in the hands of an expert might be followed by as small a mortality as gastro-enterostomy and might lead to better end-results, should it come to be regarded as the routine operation it might be followed by deplorable results. Finney's operation had not been given up in America, and there was a slight tendency in recent years to resort to it somewhat more frequently.

Prof. D. P. D. **Wilkie** (Edinburgh) thought that most surgeons were satisfied with gastro-enterostomy as relief of the symptoms so often followed, and unfortunate sequelæ were very rare, particularly in duodenal ulcer. Where the stomach was hypertonic or the ulcer inclined to bleed freedom from symptoms followed only in 50 per cent. It had little effect on the large florid ulcer. He did not consider gastrectomy had stood the test of time. The stomach was not a useless organ as was sometimes supposed, and after gastrectomy he had felt that he was not justified in removing so much of it for so small a lesion. He now performed a posterior gastro-enterostomy and whenever possible excised the ulcer, otherwise he infolded it. The bad results were due to faulty technique and the wrong choice of cases. Two conditions were apt to follow—jejunal ulcer and bilious vomiting. The former was due to hyperacidity and could be prevented by effective post-operative treatment, while the latter was often due to too small an opening in the mesocolon.

Thursday, July 22nd

Carcinoma of the Tongue

The discussion was opened by Mr. **Duncan Fitzwilliams** (London), who began by emphasising the need for a preliminary cleansing of the ulcer and of the mouth for some days before operation, when the patient should accustom himself to swallowing from the feeding tube. He always used warmed ether as the anæsthetic and did a preliminary laryngotomy to avoid ligature of the lingual artery. Intratracheal ether had the drawback that the introduction of the tube took time and might cause bleeding from the growth. Morphia should be given before operation only in small doses, as it interfered with the swallowing and coughing reflexes, and should be avoided as far as possible in the after-treatment. He removed the tongue first by scissors and knife and did not employ diathermy, and waited about a fortnight for the wound to heal before removing the glands. As the primary growth was removed there was no tendency for the cancer to spread in the interval. The carcinoma does not extend laterally along the mucous membrane, but deeply into the substance of the tongue. Consequently, even if a full three-quarters of an inch of healthy tissue were removed around the growth, enough mucous membrane would be left to allow of the margins being sutured together. In this way a large ulcerating wound was avoided, there was much less pain, and much less tendency to the development of broncho-pneumonia. At the end of the operation the plugging was removed from the pharynx and the laryngotomy tube withdrawn, when the patient was able to breathe through the natural channels. He removed the glands by the block dissection of Crile, but did not touch the opposite side of the neck unless the glands on the same side were much involved.

Sir **William Milligan** (Manchester) dealt with the treatment by radio-diathermy. Where the primary growth was operable, and the lymphatic involvement not too great, surgical removal was always indicated. If this were to be done he did not consider previous irradiation of the neck should be carried out, as it interfered with the successful removal of the growth. Radium and diathermy should be reserved for inoperable cases or when operation was refused. Even if a cure did not take place, they often did good by giving complete freedom from symptoms even for years, and relieved the pain, prevented hæmorrhage, and diminished the dysphagia. When surgical intervention was deemed impracticable owing to the extent of the growth an attempt should be made to remove it by the diathermy knife or to destroy it by the diathermy button. When the removal of the growth is contra-indicated, radium should be inserted into its substance. The lingual artery should invariably be tied. Screened tubes might be buried in the growth, but owing to action of beta rays being more local than gamma, they were apt to produce necrosis, followed by sepsis if retained for more than 48 hours. Further, it was impossible to keep screened tubes accurately in position in a mobile organ such as the tongue. Consequently he had been implanting into the substance of the growth large numbers of "seeds" containing emanation. These should be placed in parallel rows 1 cm. apart, when they became encapsuled or sloughed out, the action being due to a devitalisation of the malignant cells. Irradiation of the lymphatic fields should be an invariable post-operative procedure. The best method was to implant screened tubes, otherwise the surface application of radium or treatment by X rays should be carried out. Of 812 cases treated in this way, all of which were in an advanced stage and inoperable, 51 had remained well for periods varying from one to nine years. Unscreened tubes were employed in 41 of these, and he believed it would be the method of the future. Treatment by radium was still, however, in its experimental stage, and it was inadvisable to be dogmatic on the value of any method.

Mr. W. S. **Dickie** (Middlesbrough) dealt with cancer of the postero-lateral part of the tongue, which usually arose in the anterior pillar of the fauces. The jaw dominated the surgery of the tongue, and he removed the lower jaw on that side together with the coronoid process and the condyle after dividing it at the canine fossa. He then removed the half of the tongue, the tonsils, and both pillars of the fauces. Later he attacked the glands, but did not do a block dissection, as recurrence took place only in the upper part of the neck. The operative mortality was high and among 17 cases there were 4 deaths, 5 had in the meantime died of recurrences, but 8 were still alive. Two cases were shown, one done four years ago. There was remarkably little disfigurement, the mouth could be fully opened, and there was little alteration in the voice.

Mr. **Gordon Taylor** (London) considered that the disease was seen only in those who had had syphilis or who had neglected mouths. Of the cases operated upon before the war all except one had died within a year. For the last five and a half years he had removed the tongue with the diathermy knife, taking away part of the alveolar margin to gain access. He later proceeded to do a block dissection of the glands on that side of the neck, even if enlarged glands were present. If enlarged glands were detected during the operation he proceeded to do a complete block dissection on the opposite side of the neck as well, otherwise he removed only the glands in the upper part. Of the cases that recovered 50 per cent were now alive and well—a big improvement. There was, however, a high operative mortality, 95 per cent of the deaths being due to broncho-pneumonia and taking place by the third day. He introduced a drainage-tube through a stab wound in the floor of the mouth to prevent the infected material being aspirated into the lungs. While a laryngotomy facilitated removal of the tongue, it did not prevent the onset of broncho-pneumonia. The three stages of the operation could, if necessary, be done under local anæsthesia.

products including insulin, glandular extracts compressed tablets and surgical sundries —[1] Parke, Davis and Co (51, Beak-street London W. 1) had a number of pharmaceutical preparations vaccines, and gland products including a new type of bacterial antigen which can be used either prophylactically or therapeutically It is believed to be the greatest advance yet made, is free from cells and toxic matter and nearly free from protein and so can be used in acute conditions. Four types are prepared—streptococcal gonococcal pneumococcal, and pertussis. Also the most potent scarlet fever streptococcus antitoxin yet produced and toxin for the Dick test

Sanocrysin was demonstrated for the first time in this country but is not on the open market owing to its danger This firm guarantee their parathyroid gland tablets to contain 90 per cent of the dried gland substance —[16] Oppenheimer Son and Co Ltd (179 Queen Victoria-street E C 4) showed a selection of their Bi-Palatinoids " and 'Palatinoids , glandular products in palatable form: ' Roboleine, the vitamin food, Maglactis " a pure magnesium hydrate in suspension and instruments for the evolution of 99 per cent pure oxygen gas from chemical cubes —[19] Schering Ltd (3, Lloyd's-avenue, London E C 3) showed a selection of their well-known products Atophan ' 'Veramon ' Medinal' also 'Maturin ' a test believed to give 90 per cent accurate results in the diagnosis of early pregnancy —[21] W A Wharram Ltd (31, Lady-lane Leeds) showed popular pepsin preparations including 'Liq Bismuth Co c Pepsin , 'Linctus Heroin Hydrochlor c Terpin Hyd ' of which each fluid drachm is equivalent to 1 12 gr of the alkaloid · Mist Neurasthen Conc', 'Syrup Hypophosph Co containing the combined hypophosphites in a neutral form a soothing antiseptic Boraline Cream ' and an analgesic ointment —[26] The Anglo-American Oil Co. Ltd (Albert-street Camden Town London N W 1) showed their paraffin products "Nujol. 'Cream of Nujol with Agar and 'Mistol also Flit the general household insecticide —[27] The Crookes Laboratories (22 Cheney-street London W C 1) showed a selection of Collosols particularly Collosol Lead M A, Collosol Lactalumina a neutral preparation of aluminium hydroxide which neutralises acidity by colloidal attraction. Collosol Ichthyol and Collosol Silica with *Drosera rotundifolia* They also distributed an "Index of Treatment," containing prescriptions bibliography, and price list —[41] The British Drug Houses, Ltd (London N 1) exhibited medical specialties including Æther Puriss B D H the Borocaines; Caprokol a new synthetic hexyl-resorcinol preparation; thyroxine tablets; and a series of microscopic stains —[42] Messrs Allen and Hanburys Ltd (Bethnal Green E 2) in addition to their 'Byno and Polyglandin" preparations showed two new substances: "Acidophilus Jelly, an agar culture of *B acidophilus*, and Cellulose Flour, a preparation for adding bulk to a diet They also showed a useful vacuum extractor a double-ended needle connected with a vacuum bottle —[48] The Hoffmann-La Roche Chemical Works, Ltd (7 and 8 Idol-lane London E C 3) showed their Allonal, "Sedobrol," and "Somnifaine" hypnotics and their new synthetic non-toxic purgative Isacen " which acts only on the intestines and is excreted unchanged —[50] Evans Sons Lescher and Webb Ltd (56, Hanover-street Liverpool), had an extensive list of hypodermic ampoules, filled by a machine which ensures accuracy and sterility, "Cascaromat ' a concentrated elixir of cascara free from bitterness: standardised Infundibulin · Marrophos ' a tonic food Purgoids ' a safe laxative tablet, 'Sexatone pluriglandular tablets, and Sodium Morrhuate for tuberculosis —[53] G W. Carnrick Co (London agents: Brooks and Warburton, Ltd 40–42 Lexington-street London, W 1) showed their glandular products including hormotone and trypsogen guaranteed to be made from fresh glands analysed and standardised, and packed in specially sealed amber glass moisture-proof bottles —[59] Armour and Co Ltd (Queen's House Kingsway, London W C 2), showed their medicinal products of animal origin, including corpus luteum guaranteed to be prepared from the ovary of the pregnant sow, pig spleen preparation in elixir and hypodermic solutions for anæmia or mild ganglionic lesions, and oxalised 'Thromboplastin' solution also capsules of 'Thyro-Manganese ' , and a double-strength 1 c cm ampoule of pituitary extract —[67] Genatosan, Ltd (Loughborough Leicestershire), showed their well-known "Genasprin," Sanatogen," 'Formamint " &c and a range of detoxicated vaccines This firm have recently been appointed the sole concessionaires in this country for the products of the Pasteur Laboratories —[73] Sandoz Chemical Co Ltd (Bradford) showed "Femergin '(ergotamine tartrate), "Felamine" 'Scillaren ' Lobeline," also a new "Allisatin" tablet for tasteless administration of *Allium sativum* —[81] J C Eno, Ltd ('Fruit Salt Works Pomeroy-street New Cross London S E 14), had an exhibit of their well-known effervescing saline laxative —[37] Jeyes Sanitary Compounds Co Ltd, (64 Cannon-street London England) showed their Cyllin' preparations Liquid soap guaranteed equal to 50 per cent carbolic acid; Lano-cyllin, an antiseptic ointment, Jeysol identical with lysol and making a clear solution Medical Cyllin has a Rideal-Walker coefficient of 24–26 for *B typhosus*

SURGICAL INSTRUMENTS AND APPLIANCES

[3] Down Bros Ltd (21 and 23 St Thomas's-street, London S E 1) showed a selection of new instruments and modifications of existing patterns including Cubley's tracheotomy instruments as used at the M A B hospitals Ivan Magill's new portable intratracheal apparatus a recent improvement demonstrated at the sectional meeting Geoffrey Marshall's portable pneumothorax apparatus, Schoemaker's stomach-crushing clamps and forceps and their Up-to-date operation table with oil pressure pump for raising and lowering with recent improvements —[9] The Genito Urinary Manufacturing Co Ltd (64, Great Portland-street, London W 1) sole agents for J Eynard Paris in Great Britain and Ireland, showed a series of surgical and optical instruments including new boilable cystoscopes, made to the pattern of leading surgeons a large improved diathermy machine with dry spark gap, boilable and non-conducting retractors and other diathermy instruments; Chevalier Jackson's improved models, Mr Norman C Lake's suction apparatus; and specialties in stainless steel by Eynard —[11] Arnold and Sons (John Bell and Croyden, Ltd) (50–52, Wigmore-street London W 1) showed a new pedestal operation table on oil-pump base, as supplied to the Cancer Hospital, the 'Arnold" high-pressure steam and vacuum steriliser for dressings, with improved radial arm wheel door; an improved urological table and chair combined: the "Mayboil" flexible elastic gum catheters and bougies, a syringe for regional anæsthesia designed by Mr O Stanley Hillman F R C S, and "Phonophore" stethoscopes —[22] Mayer and Phelps (Chiron House, 59-61, New Cavendish-street London W 1) showed instruments and apparatus of original design, many in stainless steel, the "Leeds" anæsthetic outfit combining apparatus for nitrous oxide, oxygen carbon dioxide, open and closed ether and chloroform; a chair for operation work in the upright position; Hammond's combined urological syringe for injecting the anterior and posterior urethra for local anæsthesia hypodermic intramuscular and intravenous injection and lumbar puncture, a novel gag for adenoid and tonsil operations: and an artificial larynx and various forms of speaking apparatus for use after total laryngectomy. —[33] The Surgical Manufacturing Co. Ltd (83 and 85, Mortimer-street London, W.1) exhibited a series of instruments including the "Barton" sphygmomanometer, the "Bard Parker knife with removable blades; the Boyle-Davis mouth gag; the "Aurora-

pressure should be taken before and every five minutes during the operation The systolic pressure alone is of little value, and more importance should be attached to the diastolic pressure and the pulse pressure A comparison of these with the pulse-rate gave the earliest warning of the onset of shock, which might be prevented by the immediate administration of intravenous saline 3 The administration of nitrous oxide and oxygen alone Nitrous oxide acts only by depriving the brain of oxygen, and it did not affect the cells of other organs such as the heart and kidneys. Its action ceased immediately its administration was stopped It was possible, provided the anæsthetist had thoroughly learnt the technique and the surgeon was gentle with his manipulations, to obtain complete relaxation in all abdominal operations, and consequently there was no necessity for ether or local infiltration Post-operative nausea and vomiting were extremely rare, and the patient came round without any struggling 4 In the preliminary treatment active purgation should be avoided and fluids should be given up to within half an hour of the operation Morphia, gr ⅙, with scopolamine, gr 1/200, should be given two hours before the operation and repeated in an hour's time. During an operation he avoided the extreme Trendelenburg position even for pelvic operations, as it predisposed to shock Nitrous oxide-oxygen anæsthesia was quite suitable for cases of intestinal obstruction provided the intestinal contents were aspirated by an electrical suction pump through a small incision immediately the abdomen was opened In these cases intravenous saline was administered from the start.

Dr C **Langton Hewer** (London) stated that gastric surgery made large demands upon the anæsthetist as it was that part of the abdomen in which respiratory movement was at its maximum, and relaxation might be difficult to produce as traction upon the peritoneum might result in laryngeal spasm In addition shock and pulmonary complications were more liable to follow than after operations elsewhere He considered that endotracheal nitrous oxide-oxygen-ether anæsthesia was preferable to regional and splanchnic anæsthesia When the patient was fully anæsthetised a tracheal catheter was slipped between the vocal cords and a mixture of 50 per cent nitrous oxide and 50 per cent oxygen passed through ether was first employed The amount and proportions of the gases were regulated until the colour of the mucous membrane was just pink and the manometer showed a pressure of 5 mm. Hg on inspiration At the end of the anæsthesia a mixture of 90 per cent oxygen and 10 per cent carbon dioxide was substituted in order to stimulate the respiratory centre and so cause forced breathing and the expulsion of the ether To avoid pulmonary complications atropine should be given in small doses repeated after the operation about 1/200 gr three times a day for three days being usually employed. In this way a perfect anæsthesia for upper abdominal work was obtained, and when once a surgeon had operated with it he almost invariably preferred it for his other cases It was suitable for cases of intestinal obstruction as, should vomiting occur, owing to the positive pressure in the lungs there was no tendency for the vomit to be aspirated into the lungs

Mr **Gordon Taylor** said that he employed local infiltration of the abdominal wall together with splanchnic anæsthesia by the posterior method of Kappis and a light ether anæsthesia from the start The latter abolished all psychical shock, made the injection of the novocaine more easy, and less morphia and scopolamine were needed In addition, should the local and splanchnic anæsthesia fail towards the end of a long operation the general anæsthesia could be easily deepened The objection to the combined method was that the injection of the splanchnics by the posterior method took time and a sudden fall in the blood pressure might ensue The latter was only temporary and was associated with no rise in the pulse-rate The advantages were that pneumonia and chest complications were almost completely eliminated, long operations could be performed with little shock, there was complete relaxation, and the breathing was very quiet In the lower abdomen he used spinal with caudal anæsthesia

Mr K. W **Monsarrat** (Liverpool) considered that no one method should be used as a routine, and the condition of the patient should be given due consideration With a powerful stout man gas and oxygen did not suffice and a general anæsthetic was necessary Where there was a liability to chest trouble he preferred warm ether given by the Shipway method With a general anæsthesia regional anæsthesia or local infiltration should always be carried out as it aided relaxation and prevented that collapse which followed if the skin incision were made when the anæsthesia was very light In operation upon the stomach and bowel he infiltrated the mesentery It was important to recognise the action of ether upon the pancreas Ketosis and acidosis might follow its use and were associated with changes in the blood-sugar These with the post-anæsthetic vomiting could be relieved by the injection of 10 units of insulin immediately after the operation, which could be repeated if necessary He strongly advised a preliminary consultation between the surgeon and the anæsthetist

Mr J P **Lockhart-Mummery** (London) considered that as yet we had not a very satisfactory local anæsthetic, as novocaine did not in all cases have sufficient penetrating powers Parasacral anæsthesia took longer than, and had no advantage over, spinal anæsthesia The fall in blood pressure that took place in the latter was purely mechanical and could be prevented by slightly tilting the table He now used regional or spinal anæsthesia combined with gas and oxygen For cases of acute intestinal obstruction he employed high spinal anæsthesia

Mr **Cade** considered that splanchnic anæsthesia had its dangers One was the intravenous injection of novocaine might occur and was dangerous as it led to a sudden fall in the blood pressure, it could be prevented by repeatedly withdrawing the piston during the injection A delayed reaction shown by a fall in the blood pressure and a rise in the pulse-rate might take place about the second day. He did not consider a general anæsthetic was necessary, as any psychical action could be avoided by the proper administration of hypnotics We were, he thought, too apt to refer to the possible damaging action of ether, while ignoring that which might result from large doses of drugs.

EXHIBITION OF DRUGS, INSTRUMENTS, FOODS, AND APPLIANCES

The usual trade exhibition was opened in the Victoria Halls on Tuesday, July 20th The Mayor welcomed the Association and called on the President-Elect to open the exhibition Mr **Hogarth** said that the display had now become an essential and integral part of the annual meeting, and emphasised the debt of the profession to the firms which supplied them with their tools. There was true coöperation between them and the profession

There were 84 stalls, and a brief notice of the more important exhibits on each is given below

Drugs and Pharmaceutical Preparations

[1] Burroughs Wellcome and Co (The Wellcome Foundation, Ltd, Snow Hill Buildings, London, E C 1) had their exhibit ingeniously arranged on different coloured panels, each of which corresponded with an organ similarly coloured on a large anatomical chart Of their many "Tabloid," "Hypoloid," and "Soloid" products may be mentioned "Tabloid" Digitalis Leaf, grown in this country, physiologically standardised and containing the active principle, "Tabloid" hypodermic insulin hypochloride the only compressed British insulin, and the "Wellcome" Brand materials for Schick and Dick tests, diphtheria prophylactic and diphtheria and scarlet fever antitoxins —[2] Boots Pure Drug Co, Ltd (Station Street, Nottingham), showed a large selection of their

products, including insulin, glandular extracts, compressed tablets and surgical sundries —[1] Parke, Davis and Co (51, Beak-street, London, W. 1) had a number of pharmaceutical preparations vaccines, and gland products, including a new type of bacterial antigen, which can be used either prophylactically or therapeutically It is believed to be the greatest advance yet made, is free from cells and toxic matter, and nearly free from protein and so can be used in acute conditions Four types are prepared—streptococcal gonococcal, pneumococcal, and pertussis Also the most potent scarlet fever streptococcus antitoxin yet produced and toxin for the Dick test ' Sanocrysin ' was demonstrated for the first time in this country, but is not on the open market owing to its danger This firm guarantee their parathyroid gland tablets to contain 90 per cent of the dried gland substance —[16] Oppenheimer, Son and Co Ltd (179 Queen Victoria-street, E C 4) showed a selection of their "Bi-Palatinoids" and "Palatinoids", glandular products in palatable form "Roboleine," the vitamin food, "Maglactis," a pure magnesium hydrate in suspension, and instruments for the evolution of 99 per cent pure oxygen gas from chemical cubes —[19] Schering, Ltd (3, Lloyd's-avenue London E C 3), showed a selection of their well-known products Atophan," "Veramon," ' Medinal ' also "Maturin" a test believed to give 90 per cent accurate results in the diagnosis of early pregnancy —[21] W A Wharram, Ltd (31, Lady-lane, Leeds) showed popular pepsin preparations including "Liq Bismuth Co c Pepsin', "Linctus Heroin Hydrochlor c Terpin Hyd" of which each fluid drachm is equivalent to 1/12 gr of the alkaloid "Mist Neurasthen Conc ', "Syrup Hypophosph Co ' containing the combined hypophosphites in a neutral form a soothing antiseptic Boraline Cream ', and an analgesic ointment —[26] The Anglo-American Oil Co, Ltd (Albert-street Camden Town London N W 1), showed their paraffin products "Nujol" "Cream of Nujol with Agar ' and 'Mistol ', also "Flit" the general household insecticide —[27] The Crookes' Laboratories (22 Chenies-street London W C 1) showed a selection of Collosols particularly Collosol Lead M A , Collosol Lactalumina, a neutral preparation of aluminium hydroxide which neutralises acidity by colloidal attraction, Collosol Ichthyol, and Collosol Silica with *Drosera rotundifolia* They also distributed an "Index of Treatment," containing prescriptions bibliography, and price list —[11] The British Drug Houses, Ltd (London, N 1), exhibited medical specialties, including Æther Puriss B D H , the Borocaines, Caprokol, a new synthetic hexyl-resorcinol preparation, thyroxine tablets, and a series of microscopic stains —[42] Messrs Allen and Hanburys, Ltd (Bethnal Green, E 2), in addition to their "Byno" and "Polyglandin" preparations, showed two new substances "Acidophilus Jelly," an agar culture of *B acidophilus*, and Cellulose Flour, a preparation for adding bulk to a diet They also showed a useful vacuum extractor, a double-ended needle connected with a vacuum bottle —[48] The Hoffmann-La Roche Chemical Works, Ltd (7 and 8, Idol-lane, London, E C 3), showed their "Allonal," "Sedobrol," and "Somnifaine" hypnotics, and their new synthetic non-toxic purgative "Isacen," which acts only on the intestines and is excreted unchanged —[50] Evans Sons, Lescher and Webb, Ltd (56, Hanover-street, Liverpool), had an extensive list of hypodermic ampoules, filled by a machine which ensures accuracy and sterility, "Cascaromat" a concentrated elixir of cascara free from bitterness, standardised Infundibulin"; "Marrophos" a tonic food, "Purgoids" a safe laxative tablet, "Sexatone" pluriglandular tablets, and Sodium Morrhuate for tuberculosis —[53] G W Carnrick Co (London agents Brooks and Warburton, Ltd, 40–42, Lexington-street, London, W 1) showed their glandular products including hormotone and trypsogen guaranteed to be made from fresh glands, analysed and standardised, and packed in specially sealed amber glass moisture-proof bottles —[59] Armour and Co, Ltd (Queen's House, Kingsway, London, W C 2), showed their medicinal products of animal origin, including corpus luteum guaranteed to be prepared from the ovary of the pregnant sow, pig spleen preparation in elixir and hypodermic solutions, for anæmia or mild ganglionic lesions, and oxalised "Thromboplastin' solution, also capsules of "Thyro-Manganese", and a double strength 1 c cm. ampoule of pituitary extract —[67] Genatosan, Ltd (Loughborough, Leicestershire), showed their well-known "Genasprin," "Sanatogen," "Formamint," &c and a range of detoxicated vaccines This firm have recently been appointed the sole concessionaires in this country for the products of the Pasteur Laboratories —[73] Sandoz Chemical Co, Ltd (Bradford), showed "Femergin" (ergotamine tartrate), "Felamine," "Scillaren," "Lobeline," also a new "Allisatin" tablet for tasteless administration of *Allium sativum* —[81] J C Eno, Ltd ("Fruit Salt" Works, Pomeroy-street, New Cross London, S E 14), had an exhibit of their well-known effervescing saline laxative —[37] Jeyes Sanitary Compounds Co, Ltd (64 Cannon-street London England), showed their ' Cyllin ' preparations Liquid soap guaranteed equal to 50 per cent carbolic acid, Lano-cyllin, an antiseptic ointment, Jeysol identical with Lysol and making a clear solution Medical Cyllin has a Rideal-Walker coefficient of 21–26 for *B typhosus*

SURGICAL INSTRUMENTS AND APPLIANCES

[3] Down Bros Ltd (21 and 23, St Thomas's-street, London S E 1), showed a selection of new instruments and modifications of existing patterns, including Cubley's tracheotomy instruments, as used at the M A B hospitals, Ivan Magill's new portable intratracheal apparatus, a recent improvement demonstrated at the sectional meeting, Geoffrey Marshall's portable pneumothorax apparatus, Schoemaker's stomach-crushing clamps and forceps, and their ' Up-to-date operation table with oil pressure pump for raising and lowering, with recent improvements —[9] The Genito-Urinary Manufacturing Co, Ltd (61, Great Portland-street, London, W 1) sole agents for J Eynard, Paris in Great Britain and Ireland showed a series of surgical and optical instruments, including new boilable cystoscopes, made to the pattern of leading surgeons, a large improved diathermy machine with dry spark gap, boilable and non-conducting retractors, and other diathermy instruments, Chevalier Jackson's improved models, Mr Norman C Lake's suction apparatus, and specialties in stainless steel by Eynard —[11] Arnold and Sons (John Bell and Croyden, Ltd) (50–52, Wigmore-street, London, W 1) showed a new pedestal operation table on oil-pump base, as supplied to the Cancer Hospital, the "Arnold" high-pressure steam and vacuum steriliser for dressings, with improved radial arm wheel door, an improved urological table and chair combined; the "Mayboil" flexible elastic gum catheters and bougies, a syringe for regional anæsthesia designed by Mr O Stanley Hillman, F R C S, and "Phonophore" stethoscopes —[22] Mayer and Phelps (Chiron House, 59-61, New Cavendish-street, London, W 1) showed instruments and apparatus of original design, many in stainless steel, the "Leeds" anæsthetic outfit combining apparatus for nitrous oxide, oxygen, carbon dioxide, open and closed ether and chloroform, a chair for operation work in the upright position; Hammond's combined urological syringe for injecting the anterior and posterior urethra, for local anæsthesia, hypodermic, intramuscular and intravenous injection and lumbar puncture, a novel gag for adenoid and tonsil operations and an artificial larynx and various forms of speaking apparatus for use after total laryngectomy. —[33] The Surgical Manufacturing Co, Ltd (83 and 85, Mortimer-street, London, W 1) exhibited a series of instruments, including the "Barton" sphygmomanometer, the "Bard Parker" knife with removable blades; the Boyle-Davis mouth gag, the "Aurora-

pressure should be taken before and every five minutes during the operation The systolic pressure alone is of little value, and more importance should be attached to the diastolic pressure and the pulse pressure A comparison of these with the pulse-rate gave the earliest warning of the onset of shock, which might be prevented by the immediate administration of intravenous saline 3 The administration of nitrous oxide and oxygen alone Nitrous oxide acts only by depriving the brain of oxygen, and it did not affect the cells of other organs such as the heart and kidneys Its action ceased immediately its administration was stopped It was possible, provided the anæsthetist had thoroughly learnt the technique and the surgeon was gentle with his manipulations, to obtain complete relaxation in all abdominal operations, and consequently there was no necessity for ether or local infiltration Post-operative nausea and vomiting were extremely rare, and the patient came round without any struggling 4 In the preliminary treatment active purgation should be avoided and fluids should be given up to within half an hour of the operation Morphia, gr. ⅙, with scopolamine, gr. 1/200, should be given two hours before the operation and repeated in an hour's time During an operation he avoided the extreme Trendelenburg position even for pelvic operations, as it predisposed to shock Nitrous oxide-oxygen anæsthesia was quite suitable for cases of intestinal obstruction provided the intestinal contents were aspirated by an electrical suction pump through a small incision immediately the abdomen was opened In these cases intravenous saline was administered from the start

Dr C Langton Hewer (London) stated that gastric surgery made large demands upon the anæsthetist as it was that part of the abdomen in which respiratory movement was at its maximum, and relaxation might be difficult to produce as traction upon the peritoneum might result in laryngeal spasm. In addition shock and pulmonary complications were more liable to follow than after operations elsewhere He considered that endotracheal nitrous oxide-oxygen-ether anæsthesia was preferable to regional and splanchnic anæsthesia When the patient was fully anæsthetised a tracheal catheter was slipped between the vocal cords and a mixture of 50 per cent nitrous oxide and 50 per cent oxygen passed through ether was first employed The amount and proportions of the gases were regulated until the colour of the mucous membrane was just pink and the manometer showed a pressure of 5 mm Hg on inspiration At the end of the anæsthesia a mixture of 90 per cent oxygen and 10 per cent carbon dioxide was substituted in order to stimulate the respiratory centre and so cause forced breathing and the expulsion of the ether To avoid pulmonary complications atropine should be given in small doses repeated after the operation about 1/200 gr three times a day for three days being usually employed In this way a perfect anæsthesia for upper abdominal work was obtained, and when once a surgeon had operated with it he almost invariably preferred it for his other cases It was suitable for cases of intestinal obstruction as, should vomiting occur, owing to the positive pressure in the lungs there was no tendency for the vomit to be aspirated into the lungs

EXHIBITION OF DRUGS, INSTRUMENTS, FOODS, AND APPLIANCES

The usual trade exhibition was opened in the Victoria Halls on Tuesday, July 20th The Mayor welcomed the Association and called on the President-Elect to open the exhibition Mr Hogarth said that the display had now become an essential and integral part of the annual meeting, and emphasised the debt of the profession to the firms which supplied them with their tools. There was true cooperation between them and the profession

There were 84 stalls, and a brief notice of the more important exhibits on each is given below

Drugs and Pharmaceutical Preparations

[1] Burroughs Wellcome and Co (The Wellcome Foundation, Ltd , Snow Hill Buildings, London, E C 1) had their exhibit ingeniously arranged on different coloured panels, each of which corresponded with an organ similarly coloured on a large anatomical chart Of their many "Tabloid," "Hypoloid," and "Soloid" products may be mentioned "Tabloid" Digitalis Leaf, grown in this country, physiologically standardised and containing the active principle, "Tabloid" hypodermic insulin hypochloride the only compressed British insulin and the "Wellcome" Brand materials for Schick and Dick tests, diphtheria prophylactic and diphtheria and scarlet fever antitoxins —[2] Boots Pure Drug Co , Ltd (Station-treet, Nottingham), showed a large selection of their s

Birmingham), showed the "Lawson Tait" special bedsteads for heart cases, for the Fowler position and for steady wheeling and standing.—[12] Hoskins and Sewell, Ltd (Bordesley, Birmingham), showed the new castor-pad fitting bed which can be wheeled on rubber-tyred castors or lowered on to rubber pads, the Sir Charles Brown Invalid Pan bedstead for bedridden cases, several special beds, lockers and slip-on bed rests the latter combined with "Burton's donkey" make a useful portable "Fowler" position apparatus

SPAS AND MEDICINAL AND MINERAL WATERS

[20] Harrogate drew attention to the recent development of their Nose and Throat and Ultra-violet treatment departments and the careful training of the Bathing Establishments staff —[31] Buxton has recently instituted a three-weeks' course "Cure Ticket" for £3 3s to dispose of the idea that spa treatment is expensive there is a new heating installation which, by means of calorifiers, keeps up a steady temperature of 150° F, thus retaining the gas in the water —[68] Droitwich has extended its hotel accommodation and has introduced freshly distilled water and "Wychna," a saline aperient water —[74] The Bath exhibit included a number of photographs, old prints and water-colour drawings and booklets describing the spa treatment and hotel accommodation —[38] Ingram and Royle, Ltd (45, Belvedere-road, London S E 1), displayed their bottled products, Vichy Celestins Contrexéville "Pavillon," Evian Cachat, Carlsbad Hunyadi Janos, &c —[60] W Gaymer and Sons, Ltd (Attleborough), showed their Cyder recommended for gout and rheumatism, and their "Perry" a sweeter pear drink —[11] Alexander Riddle and Co Ltd (58–60, Bancroft-road London E 1) showed their vitamin C drinks, Stowers' lime juice, and lemon and orange squash

FOOD PRODUCTS

[23, 29, 79] Horlick's Malted Milk Co, Ltd (Slough, Bucks), Benger's Food, Ltd (Otter Works, Manchester) and Virol Ltd (Hanger-lane Ealing, London, W 5), showed their well-known products Horlick's malted milk food and tablets, Benger's Food and digestive preparations; Virol, Virol and milk and Virolax —[28] Oxo, Ltd (Thames House, Queen-street-place, London, E C 4), drew attention to their unseasoned hospital Oxo, meat juice, and endocrine preparations standardised by physiological and chemical methods —[32] Glaxo (56, Osnaburgh-street, London, N W 1), in addition to Glaxo and Glax-Ovo, presented particularly their vitamin D preparation, "Ostelin" for promoting the absorption of calcium and phosphorus while avoiding the intolerance often shown towards other forms of cod-liver oil Ostelin is also prepared with malt extract and orange juice —[35] Trufood, Ltd (the Creameries, Wrenbury, Cheshire and Lever House, Blackfriars, E C 4), were showing Humanised Trufood, a spray milk closely analogous to human milk, Trufood Full-cream and Secway, a concentrated and very assimilable form of nourishment —[45] Cadbury Bros, Ltd (Bournville, England), had on their stand their different makes of chocolate, and drew attention to their special method of making cocoa so as to bring out the full flavour —[46] Keen, Robinson and Co, Ltd (Carrow Works, Norwich), showed "Almata," a complete synthetic food for infants and invalids, Robinson's "Patent" barley, groats, and Waverley oats, and Keen's mustard ointment, designed to take the place of mustard plasters —[52] Montgomerie and Co, Ltd (Ibrox Glasgow), showed "Berna" food for infants and adults and "Berna" malted food, which is largely used in hospitals and is particularly useful for the expectant mother —[54] Mead's Infant Diet Materials (Brooks and Warburton A D S Co), Ltd (40–42, Lexington-street, London, W 1), showed Mead's "Recolac," a reconstituted milk in which even the salts are prepared so as to correspond closely with human milk, the well-known "Dextri-maltose", protein milk and milk soup for sick infants, and a biologically standardised and tested Newfoundland cod-liver oil (Empire product) which has little taste or odour —[69] Brusson Foods, Ltd (311, Gray's Inn-road, London, W C 1), showed Brusson breads for diabetes and a gluten chocolate sweetened with saccharin —[77] S Guterman and Co, Ltd (35–6, Aldermanbury, London, E C 2) showed "Cereal Meal," a combination of cereal, agar-agar, flax-seed meal, and bran designed to produce large, soft easy evacuations They also showed a simple light and heat ray lamp, the "Adjusto Ray"

BOOKS

The following publishing houses had each a large series of interesting publications, of which only a few can be mentioned [8] H K Lewis and Co, Ltd (136–140, Gower-street, London, W C 1) "Health Legislation" by F Harvey; "Epilepsy a Functional Mental Illness" by R G Rows and W E Bond, Timbrell Fisher's "Manipulative Surgery", E M Brockbank's "Incapacity or Disablement in its Medical Aspects", L R Fifield's "Minor Surgery", and "The Clinical Examination of the Nervous System," by G H Monrad-Krohn —[17] J and A Churchill (7, Great Marlborough-street London, W 1) The "Recent Advances" series, including Obstetrics and Gynaecology and Biochemistry, the new edition of Craig's "Psychological Medicine," by Craig and Beaton, a new edition of Sequeira's "Diseases of the Skin" and the "Medical Directory"—[47] The Oxford University Press (Amen House, Warwick-square London, E C 4) Leonard Williams's "Obesity", Cope's "Treatment of the Acute Abdomen" and his "Early Diagnosis" in third edition, Tod's "Diseases of the Ear," fourth edition, "Pathology and Treatment of Diabetes Mellitus," by Graham, new edition, and a new series of 5s handbooks including Cameron on "Diseases of Children" and Gibson on "The Heart"—[78] John Wright and Sons, Ltd (Bristol) Geddes's "Puerperal Septicaemia", ninth edition of the "Index of Treatment" (Hutchison and Sherren); Carey Coombs's "Rheumatic Heart Disease", Lawford Knaggs's "Inflammatory and Toxic Diseases of Bone", "Urgent Surgery," by Felix Lejars, "The Cancer Review," first number, "The British Journal of Surgery" and the well-known "Synopsis" series —[84] W. B Saunders Company, Ltd (9, Henrietta-street, London W C 2) "Pediatrics," by 150 authorities, "Mayo Clinic Collected Papers, 1925", Bickham's "Operative Surgery", Berkeley Moynihan's "Abdominal Operations", Young's "Practice of Urology", G A L Morse's "Clinical Pediatrics", and "The Art of Medical Treatment" by F W Palfrey —[58] The Food Education Society (24, Tufton-street, Dean's Yard, London S W 1) showed their publications on dietetics and hygiene, including the popular "Facts for Patriots" series on food values; "The Pudding Lady's Recipe Book," and leaflets such as "The Nation's Health"

MEDICAL AGENCIES

[11] Arnold and Sons (50–52, Wigmore-street, London, W 1) had their "Medical Transfer" department represented on their stand —[55 and 56] The Medical Insurance Agency (c/o British Medical Association, B M A House, Tavistock-square, London, W C 1) had their usual literature and were also accompanied by an engineer from Mann, Egerton and Co, Ltd, to advise on all car matters —[66] The Medical Sickness, Annuity and Life Assurance Society, Ltd (300, High Holborn London, W C 1), had a representative to advise visitors on matters of life, sickness, and endowment assurance

MISCELLANEOUS

[24, 75] Among toilet preparations "Pepsodent," the acid dentifrice, and Kolynos Incorporated (Chenies-street, London, W C 1) demonstrated their well-known tooth creams —[63] The Museum Galleries (53, Short's-gardens, Drury-lane, London, W C 2) had an exhibit of engravings, including their "Gallery of 100 Famous Men and Women" and "The Cries of London," after Francis Wheatley, R.A.

scope" throat and ear apparatus, and an improved midwifery outfit —[15] Messrs Allen and Hanburys, Ltd (48, Wigmore-street, London, W 1), had a large selection of instruments, including a portable Mennell's universal voltage motor pump for blowing and sucking, Mennell's ether mixing apparatus for intratracheal anæsthesia, Howard Jones's mixing apparatus for intratracheal and open ether anæsthesia, Souttar's steam cautery; apparatus for testing the patency of the Fallopian tubes, and a complete set of gynæcological instruments as used by Comyns Berkeley and Victor Bonney, London Hospital catgut; the St Bartholomew's Hospital pattern operation table with various improvements, including ball-bearing wheels guaranteed not to require attention for ten years; and a series of the latest model Wolf boilable and large field cystoscopes —[49] Stille (Stockholm, Sweden) exhibited a selection from surgical instruments which the firm has been making from best Swedish steel since 1841 Many were of stainless steel The British agents are Ogilvy and Co, 20, Mortimer-street, London, W 1 —[70] The Holborn Surgical Instrument Co, Ltd (26, Thavies Inn, Holborn-circus, London, E C 1), showed daylight surgical lamps for ophthalmoscopy, &c, giving a white light through blue glass, the "Minop" knife with detachable blades and cases for keeping the blades in disinfectant solution, a new sphygmomanometer with unspillable tube and wider mercury column, and a large assortment of stainless steel, including pocket dressing-cases —[76] John Weiss and Son, Ltd (287, Oxford-street, London, W 1), included in their exhibit Ryall's cysto-urethroscope, a cystoscopic lithotrite, new models in ophthalmic instruments, including Bishop Harman's ring adaptable to any forceps, and Harrison Butler's squint instrument

Among the Special Instruments —[5] P H Zeal, Ltd (75 and 77, St John-street, London, E C 1), showed their "Repello" thermometer and "Acello" re-setting case, an aseptic glass clinical thermometer, and various other types of recording instruments, including surface thermometers and urinometers — [13] Rayner and Keeler, Ltd (9, Vere-street, Cavendish-square, London, W 1), showed ophthalmic instruments, including a single beam operating lamp and stand, a large model May ophthalmoscope, allowing much more light than small instruments; and Zeiss instruments, including slit lamps and corneal microscopes They also had a display series of drawings and fundus paintings —[51] Alexander and Fowler (59A, Pembroke-place, Liverpool) showed the "Constanta" truss, with moulded pelvic band, no perineal strap and control spring to the pad The special link attachment to the band allows parallelism to the abdominal wall under all conditions —[25] The Inhaling Drug and Apparatus Co, Ltd (30, Grosvenor-place, S W 1), showed the Spiess-Drager drug nebulising and inhaling apparatus for asthma, emphysema, &c —[83] Theodore Hamblin, Ltd (15, Wigmore-street, London, W 1), showed a number of ophthalmic instruments, including a recently improved Lister perimeter and scotometer, the new Lister hand projection lamp, the 1925 astigmatic chart, a new series of stereoscopic pictures designed to make the promotion of binocular vision more interesting to children, and a selection of ophthalmic drawings by Hamblin's staff of skilled draughtsmen —[18] H E Curtis and Son, Ltd (7, Mandeville-place, London, W 1) showed the "Curtis" abdominal support for ptosis and other belts and trusses, and "Kaylene," a pure hydrated silicate of alumina for gastro-intestinal intoxication, it is supplied pure and combined with saline, mint, laxative, and paraffin respectively —[39] Short and Mason, Ltd ("Tycos") (Atlantic House, 45–50, Holborn-viaduct London, E C 1) showed their "Tycos" sphygmomanometers, both portable and surgery types, standard calibration, self-verifying, jewelled movements ensuring extreme sensitivity in action

Aids for the Deaf —[36] General Acoustics, Ltd (77, Wigmore-street, London, W 1), showed their latest models in aids for the deaf, electrical and non-electrical, particularly the shell type and the small button type, and the multiple acousticon for large gatherings —[44] "Ardente Acoustique" (Mr R H Dent) (95, Wigmore-street, London, W 1) had several new small models, one ear-piece the size of a shilling, and a microphone the size of a florin; also a stethoscope for deaf doctors —[11] Arnold and Sons (John Bell and Croyden, Ltd) (50–52, Wigmore-street, London, W 1) were also showing electrical and non-electrical aids for the deaf from their stock, which includes all makes

Artificial Limbs —[40] Chas A Blatchford and Sons, Ltd (90, Clapham-road, London, S W 9), showed their new artificial leg, which is held on by suction and requires no harness of any kind, also other appliances for amputations and mutilations —[43] Pedestros, Ltd (26, Langham-street, London, W 1), had a comprehensive display of light metal limbs

X Ray and Light Apparatus —[57] Gray and Selby (27–29, Pelham-street, Nottingham) had a demonstration of British-made ultra-violet radiation apparatus, instruments, and microscopes —[62] The British Hanovia Quartz Lamp Co, Ltd (Slough), showed a number of patent models, including the water-cooled Kromayer lamp for treatment of small areas and orifices, a standard metal alpine-sun lamp for direct connexion to direct or alternating currents, with greatly improved and simplified action —[65] Ajax, Ltd (117, Central-street, London, E C 1) showed portable ultra-violet ray apparatus, including tungsten arc lamp, portable poly metallic carbon arc, Sundiray arc, and a table-model mercury-vapour quartz burner apparatus —[71] The Dowsing Radiant Heat Co, Ltd (91–93, Baker-street, London, W 1), showed apparatus for radiant heat treatment, particularly a special tungsten lamp, the "Ultra-Vi," fitted with special glass bulb and screens and suitable for home use, as it can be applied for periods up to 30 minutes —[6] Kodak, Ltd (Kingsway, London, W C 2), showed X ray negatives made on Eastman "Duplitized" film, including dental negatives, illustrating the new "Bite-wing" system for the early detection of interproximal cavities, and small positive reproductions, and a new method of cholecystography, the sensitising preparation being administered orally or by intravenous injection

ACCESSORIES AND HOSPITAL EQUIPMENT

[7] Cuxson, Gerrard and Co, Ltd (Oldbury, near Birmingham), showed a range of "Sanoid" catgut, sterilised in triplicate, an assortment of surgical and medical plasters, including rubber adhesive strapping on holland for orthopædic work, and the "Zudor" jacket for pneumonia —[82 and 34] The Thermogene Co, Ltd (Haywards Heath, Sussex), and the Denver Chemical Manufacturing Co displayed their well-known products, "Thermogene" and "Antiphlogistine"—[30] Fassett and Johnson, Ltd, exhibited a full range of Seabury and Johnson plasters, dressings, and requisites, including "Mead's" rubber adhesive plaster, "Gold Cross" absorbent cotton, and "Argyrol" silver vitelin —[61] Manlove Alliott and Co, Ltd (Bloomsgrove Works, Nottingham), showed a complete range of steam and gas-heated sterilising apparatus for hospital use, especially one with a waterlute for avoiding the collection of steam in the apparatus, and a gas incinerator for small parcels of objectionable refuse —[64] Messrs Chas Hearson and Co, Ltd (68, Willow-walk, London, S E 1), had a general research laboratory exhibit, including all-metal drying ovens, centrifuges, particularly a new high-speed model (3–10,000 revs) for ultramicroscopic viruses, and the Dartfield illuminator for spirochætes, workable off a house current —[80] Baird and Tatlock (London), Ltd (14–15, Cross-street, Hatton Garden, London, E C 1), showed laboratory apparatus, including Thompson Chard filter, Stanford's pipette, Ayling's automatic fillers, Garrow's agglutination apparatus, Schuster's respiration pump, incubators, milk sedimentation apparatus, and autoclaves, all made in their own factory at Walthamstow —[10] Whitfields Bedsteads, Ltd (109–125, Watery-lane, Bordesley,

THE LANCET.

SCIENCE AND THE STATE

THE PRINCE OF WALES has been up and down the world a good deal, and he has kept his eyes open And, as he told the British Association at Oxford in his presidential address on Wednesday evening, if a man does that he cannot help picking up a certain amount of information The tale he tells of his experiences and impressions will vary with his audience but we hardly think that it was merely in compliment to his hearers that he devoted his speech to science, progress, and the State Rather we believe that he was glad to have the opportunity of affirming in sympathetic surroundings his conviction of the high importance of scientific method and scientific knowledge to the needs of civilisation to-day Everywhere, he says as an onlooker he has seen the same thing—in factories mines education, health agriculture, transport, housing, and war—that progress consists in applied science, and that it is on the sincere pursuit of knowledge that man must depend to keep and improve his control over his surroundings and so maintain his frail body in a naturally unfriendly environment at the top of the biological hierarchy If such is the truth—and it can fail to be true only in so far as it does not take into account the whole of human life—the relation of the State to scientific work plainly becomes a matter of as much moment as any of its other organised activities, and the PRINCE traced in a most interesting way the development of this connexion, slowly and tentatively during the nineteenth century, quicker in the twentieth, and then with a rush which got the impetus of the war behind it and gave us the Medical Research Council, the Committee for Scientific and Industrial Research, the Development Commission, the National Physical Laboratory, and all the other outward and visible signs of the change in the heart of Whitehall Such is the present development of the ideas put forward by DAVID BREWSTER when he was President in 1850 and urged again from the chair by the PRINCE CONSORT in 1859 If he had lived we may be sure that PRINCE ALBERT would have given a large share of his life of laboured toil to procuring the diffusion of useful knowledge of which the invention of the 1851 Exhibition was a practical example We can trust that the present President will not let his interest flag with his year of office and that he will use his influence for the promotion of that natural knowledge of which he recognises the value so well

When the Association met in Oxford in 1832, KEBLE and others were horrified that honorary degrees should be conferred on some of the famous men who came to the meeting When the Museum was built 70 years ago, it was not with the unanimous approval of everyone But this feeling of antagonism, this strain toning down to uneasiness, has now gone or almost gone, and in few universities is natural science viewed more sympathetically and reasonably than in Oxford, indeed, it seems sometimes as if the humanities understood science better than science understood the humanities This reconciliation has not been brought about by these aspects of scientific work which are the main theme of the PRINCE's speech, the complement of which may be found in Dean INGE's Fison Memorial Lecture at Guy's Hospital Harmony has come not by realising that science enables us to fly to Amsterdam for afternoon tea, to listen to the opera on the sofa, to have a tolerably perfect apple to eat on any day of the year, but by perceiving that in its larger movements it has all the æsthetic, cultural, and spiritual value of literary studies The Victorian comparative anatomists and the Georgian physicists developed conceptions at the intellectual level, of the educational value, and with the emotional appeal of Greek and Latin literature, philosophy and history Lately philosophers and mathematicians have found that their subject matters actually overlap And natural science has won its recognition not because it is requisite for the body, but because it is necessary for the soul, and equally with the older disciplines helps men to get nearer to their ultimate goal of goodness, truth, and beauty So the dialectics of WILBERFORCE and HUXLEY, which appear to be all that anyone recalls of the second Oxford meeting in 1860, seem to us nowadays rather cheap and wholly beside the point The "*Origin of Species*" has now settled into its place in our mental fabric By the time the fifth Oxford meeting is held people at large may be clever enough to apprehend the revolution of relativity What will the presidential address then be about?

COMBINED ANÆSTHESIA IN ABDOMINAL SURGERY.

THE inter sectional discussion on anæsthesia at the recent meeting of the British Medical Association in Nottingham, reported on another page, was remarkable for the number of surgeons who took a leading part in it Prof FINSTERER, whose masterly review covered in turn the fields of general anæsthesia, of regional anæsthesia, and of combined methods, made good his point that though of much general utility, ether and chloroform have serious defects as routine anæsthetics They both cause a fall in blood pressure, they do not protect the brain efficiently from afferent impulses, they may lead to cellular degeneration in the liver, kidneys, and other parenchymatous organs, and they invite the onset of pulmonary complications From many of these defects nitrous oxide gas is free, and in America especially it has been used on an enormous scale; in Austria its use has been abandoned on account of the expense, and ether is employed by Viennese surgeons when a general anæsthetic is indispensable Recent years have, however, witnessed a remarkable development in regional methods, and these have now reached such perfection in Vienna that practically any operation can be carried out painlessly by their means Prof FINSTERER gave the strength and quantity of the novocaine solution generally employed By their use afferent impulses are so completely blocked that the patient does not suffer from post-operative toxic disturbance When, as in an extensive laparotomy, it is essential for the peritoneum of the posterior wall as well as of the anterior to be anæsthetic, this is effected either by injection of the mesentery, which even under genera

In the Marne district lived a lady who possessed a small but valuable collection of pictures She was driven out of her house by the invasion, but on her return found it intact, but no pictures Eventually she found them behind a curtain, together with the following note, written in French by a lieut -major of Hesse Darmstadt "I congratulate you on your Moreau and sundry other small pictures As an artist myself, I know their value and have put them on one side to preserve them "

The book is one to be read at leisure, and the various deeds therein described are to be wholeheartedly admired

JOURNALS

JOURNAL OF PATHOLOGY AND BACTERIOLOGY Vol XXIX No 3 Pp 225–324 July, 1926 —The Enterococcus, by S V Bagger (Copenhagen) The intestinal streptococcus known to the French as the enterocoque, but little recognised in this country under that name, is defined from a study of 150 strains It differs from other streptococci mainly in its high heat resistance and its ability to grow in bile media —An Epithelial Tumour in the Spleen of a Rabbit, by N D Ball (London). A curious formation of what appears to be intestinal epithelium which presumably represents some developmental misplacement —The Nature of the "Oat-celled Sarcoma" of the Mediastinum, by W G Barnard (London) The tumour is really a carcinoma of lung —Polyarteritis Acuta Nodosa, by J Gray (Aberdeen) A characteristic example of this curious condition, apparently following an obscure infection of the leg —The Receptor Structure of *Vibrio choleræ* (*V. comma*), with Observations on Variations in Cholera and Cholera-like Organisms, by I Balteanu (London) Like the typhoid-paratyphoid group, the cholera vibrio contains two series of antigens, heat-stable and heat-labile, and probably representing the somatic and flagellar parts of the bacillary body The author also describes an aflagellar variant growing in opaque colonies in which the heat-stable antigen was alone present in approximately normal amounts This thorough study should be consulted in detail by those interested in bacterial variation —The Third Agglutinating System in Human Blood, by F W Simson (Sheffield) The observations of Guthrie and Huck and of others on the existence of a third agglutinin and receptor (C) in human blood are fully confirmed Their existence is rarely demonstrable by direct agglutination, but absorption experiments show that either the agglutinin or the agglutinable substance is present in the serum or red corpuscles respectively of a large proportion of persons This third element makes no difference to the ordinary system of grouping, its existence, however, strengthens the conclusion that direct cross-agglutination between the proposed donor and the recipient should be practised in all transfusions —The Nutritive Requirements of Growing Cells, by T B Heaton (Oxford) Up to about the eleventh day of incubation the tissues of chick embryos grow well in a saline medium, older tissues require growth-promoting substances in addition, of which the author distinguishes two—one necessary for fibroblasts and one, abundant in yeast and possibly vitamin B, necessary for epithelia There is, too, another substance, present in yeast and in many adult mammalian organs, which inhibits the growth of fibroblasts —Complement Fixation with Bilharzia, by A. W Turner (Melbourne) Anaphylactic experiments do not confirm Le Bas's suggestion that Fairley's extract for diagnosing bilharzia infection contains protein —Carcinoid Tumour of the Ileum with Metastases, by C E Dukes and P Lockhart-Mummery (London) The basal-celled cancers of the ileo-cæcal region seldom give rise to secondary growths, which in this case were found in the peritoneum, liver, and regional lymph glands —The Influence of Locally Injected Indian Ink on the Intracutaneous Response to Vaccinia and Other Viruses, by J C G Ledingham (London) Occupation of the reticulo-endothelial system by Indian ink much diminishes or prevents the local reaction to vaccinia virus, streptococci, and diphtheria toxin —A Combination of Bismuth and Sodium Sulphite Affording an Enrichment and Selective Medium for the Typhoid-paratyphoid Groups of Bacteria, by W J Wilson and E M M'V Blair (Belfast) Another of Prof Wilson's useful pieces of technique —Proceedings of the Thirty-third Meeting of the Society —Lamb Dysentery, by T Dalling (London) The disease, in places where it generally kills 20–30 per cent of the new-born lambs, may be almost entirely prevented by dosing the lambs with a mixture of *coli* and *welchii* antisera or, more conveniently, by immunising the pregnant ewes with *coli* vaccine and a *welchii* toxin-antitoxin mixture —Aminostyryl Quinoline and Aminoanil Quinoline Compounds, by C H Browning, J B Cohen, S Ellingworth, and R Gulbransen (Glasgow and Leeds) These new trypanocidal agents have a powerful curative effect on mice and rabbits infected with *T brucei;* they are not suitable for intravenous injection —The Different Immunising Values of Vaccines Made with Smooth and Rough Forms of Bacteria, by J A Arkwright (London) The smooth form of paratyphoid A is more virulent and makes a better vaccine than the rough form —The Value of Taurine for Promoting the Growth of the Gonococcus, by J Gordon (Leeds) The effect is attributed to a lowering of surface tension and a concentration of the taurine on the surfaces of the bacilli —Immunity Produced by the Schick Test, by R A O'Brien (London) The minute doses of diphtheria toxin used in Schick tests are capable of rousing an active immunity —The Histological Criteria of Ulcer-Cancer of the Stomach, by M J Stewart (Leeds) The important evidence of chronic ulceration is destruction of the muscular coat, the pitfall in the diagnosis of carcinoma is the misinterpretation of misplaced epithelium which is much more common in the stomach than is supposed Of 260 stomachs removed surgically, 163 showed simple chronic ulcer, 80 cancer only, and 17 both

Reports and Analytical Records.

RYVITA CRISP BREAD (MIXED)

(THE RYVITA CO, 96, SOUTHWARK STREET, S E 1)

THIS crisp bread (Knäckerbrod), imported from Sweden, is prepared from crushed whole rye The crisp bread is made up in the form of perforated rectangular biscuits, 4 in by 2½ in by ⅛ in, which are very palatable, especially if eaten with butter There is more character in the flavour of rye than in wheat, and the food value of the former needs no comment

The crisp bread is sold in two forms, light and dark, the latter presumably being more heavily baked On analysis the following results were obtained —

	Light crisp bread, per cent	Dark crisp bread, per cent
Carbohydrates, altered starch, hemicellulose, &c	74 8	73 6
Protein	11 6	12 6
Moisture	9 0	9 3
Ash	1 8	2 1
Fat	1 3	1 0
Fibre	1 5	1 4
Calorie value per lb	1662	1613

Ryvita crisp bread, which keeps well and does not readily become "slack," is easily masticated and digested, and is a useful and palatable addition to the diet The calorie value shows it to be a concentrated form of food

SCIENCE AND THE STATE.

THE PRINCE OF WALES has been up and down the world a good deal and he has kept his eyes open. And as he told the British Association at Oxford in his presidential address on Wednesday evening if a man does that he cannot help picking up a certain amount of information. The tale he tells of his experiences and impressions will vary with his audience but we hardly think that it was merely in compliment to his hearers that he devoted his speech to science progress and the State. Rather we believe that he was glad to have the opportunity of affirming in sympathetic surroundings his conviction of the high importance of scientific method and scientific knowledge to the needs of civilisation to-day. Everywhere he says as an onlooker he has seen the same thing—in factories mines education health agriculture, transport housing, and war—that progress consists in applied science and that it is on the sincere pursuit of knowledge that man must depend to keep and improve his control over his surroundings and so maintain his frail body in a naturally unfriendly environment at the top of the biological hierarchy. If such is the truth—and it can fail to be true only in so far as it does not take into account the whole of human life—the relation of the State to scientific work plainly becomes a matter of as much moment as any of its other organised activities, and the PRINCE traced in a most interesting way the development of this connexion slowly and tentatively during the nineteenth century, quicker in the twentieth, and then with a rush which got the impetus of the war behind it and gave us the Medical Research Council, the Committee for Scientific and Industrial Research, the Development Commission, the National Physical Laboratory, and all the other outward and visible signs of the change in the heart of Whitehall. Such is the present development of the ideas put forward by DAVID BREWSTER when he was President in 1850 and urged again from the chair by the PRINCE CONSORT in 1859. If he had lived we may be sure that PRINCE ALBERT would have given a large share of his life of laboured toil to procuring the diffusion of useful knowledge of which the invention of the 1851 Exhibition was a practical example. We can trust that the present President will not let his interest flag with his year of office and that he will use his influence for the promotion of that natural knowledge of which he recognises the value so well.

When the Association met in Oxford in 1832, KEBLE and others were horrified that honorary degrees should be conferred on some of the famous men who came to the meeting. When the Museum was built 70 years ago, it was not with the unanimous approval of everyone. But this feeling of antagonism, this strain toning down to uneasiness has now gone or almost gone and in few universities is natural science viewed more sympathetically and reasonably than in Oxford; indeed, it seems sometimes as if the humanities understood science better than science understood the humanities. This reconciliation has not been brought about by these aspects of scientific work which are the main theme of the PRINCE'S speech the complement of which may be found in Dean INGE'S Fison Memorial Lecture at Guy's Hospital. Harmony has come not by realising that science enables us to fly to Amsterdam for afternoon tea to listen to the opera on the sofa, to have a tolerably perfect apple to eat on any day of the year but by perceiving that in its larger movements it has all the æsthetic, cultural, and spiritual value of literary studies. The Victorian comparative anatomists and the Georgian physicists developed conceptions at the intellectual level, of the educational value, and with the emotional appeal of Greek and Latin literature philosophy and history. Lately philosophers and mathematicians have found that their subject matters actually overlap. And natural science has won its recognition not because it is requisite for the body, but because it is necessary for the soul and equally with the older disciplines helps men to get nearer to their ultimate goal of goodness, truth and beauty. So the dialectics of WILBERFORCE and HUXLEY, which appear to be all that anyone recalls of the second Oxford meeting in 1860 seem to us nowadays rather cheap and wholly beside the point. The Origin of Species has now settled into its place in our mental fabric. By the time the fifth Oxford meeting is held people at large may be clever enough to apprehend the revolution of relativity. What will the presidential address then be about?

COMBINED ANÆSTHESIA IN ABDOMINAL SURGERY.

THE inter-sectional discussion on anæsthesia at the recent meeting of the British Medical Association in Nottingham, reported on another page, was remarkable for the number of surgeons who took a leading part in it. Prof. FINSTERER, whose masterly review covered in turn the fields of general anæsthesia of regional anæsthesia and of combined methods, made good his point that though of much general utility, ether and chloroform have serious defects as routine anæsthetics. They both cause a fall in blood pressure, they do not protect the brain efficiently from afferent impulses they may lead to cellular degeneration in the liver, kidneys, and other parenchymatous organs, and they invite the onset of pulmonary complications. From many of these defects nitrous oxide gas is free, and in America especially it has been used on an enormous scale; in Austria its use has been abandoned on account of the expense, and ether is employed by Viennese surgeons when a general anæsthetic is indispensable. Recent years have, however witnessed a remarkable development in regional methods and these have now reached such perfection in Vienna that practically any operation can be carried out painlessly by their means. Prof. FINSTERER gave the strength and quantity of the novocaine solution generally employed. By their use afferent impulses are so completely blocked that the patient does not suffer from post-operative toxic disturbance. When as in an extensive laparotomy, it is essential for the peritoneum of the posterior wall as well as of the anterior to be anæsthetic, this is effected either by injection of the mesentery, which even under genera

In the Marne district lived a lady who possessed a small but valuable collection of pictures She was driven out of her house by the invasion, but on her return found it intact, but no pictures Eventually she found them behind a curtain, together with the following note, written in French by a lieut -major of Hesse Darmstadt "I congratulate you on your Moreau and sundry other small pictures As an artist myself, I know their value and have put them on one side to preserve them "

The book is one to be read at leisure, and the various deeds therein described are to be wholeheartedly admired

JOURNALS

JOURNAL OF PATHOLOGY AND BACTERIOLOGY Vol XXIX No 3 Pp 225-324 July, 1926 — The Enterococcus, by S V Bagger (Copenhagen) The intestinal streptococcus known to the French as the enterocoque, but little recognised in this country under that name, is defined from a study of 150 strains It differs from other streptococci mainly in its high heat resistance and its ability to grow in bile media —An Epithelial Tumour in the Spleen of a Rabbit, by N D. Ball (London) A curious formation of what appears to be intestinal epithelium which presumably represents some developmental misplacement —The Nature of the "Oat-celled Sarcoma" of the Mediastinum, by W G Barnard (London). The tumour is really a carcinoma of lung —Polyarteritis Acuta Nodosa, by J Gray (Aberdeen) A characteristic example of this curious condition, apparently following an obscure infection of the leg —The Receptor Structure of *Vibrio choleræ* (*V. comma*), with Observations on Variations in Cholera and Cholera-like Organisms, by I Balteanu (London) Like the typhoid-paratyphoid group, the cholera vibrio contains two series of antigens, heat-stable and heat-labile, and probably representing the somatic and flagellar parts of the bacillary body. The author also describes an aflagellar variant growing in opaque colonies in which the heat-stable antigen was alone present in approximately normal amounts This thorough study should be consulted in detail by those interested in bacterial variation —The Third Agglutinating System in Human Blood, by F W Simson (Sheffield) The observations of Guthrie and Huck and of others on the existence of a third agglutinin and receptor (C) in human blood are fully confirmed Their existence is rarely demonstrable by direct agglutination, but absorption experiments show that either the agglutinin or the agglutinable substance is present in the serum or red corpuscles respectively of a large proportion of persons This third element makes no difference to the ordinary system of grouping; its existence, however, strengthens the conclusion that direct cross-agglutination between the proposed donor and the recipient should be practised in all transfusions —The Nutritive Requirements of Growing Cells, by T B Heaton (Oxford) Up to about the eleventh day of incubation the tissues of chick embryos grow well in a saline medium: older tissues require growth-promoting substances in addition, of which the author distinguishes two—one necessary for fibroblasts and one, abundant in yeast and possibly vitamin B, necessary for epithelia There is, too, another substance, present in yeast and in many adult mammalian organs, which inhibits the growth of fibroblasts — Complement Fixation with Bilharzia, by A. W Turner (Melbourne) Anaphylactic experiments do not confirm Le Bas's suggestion that Fairley's extract for diagnosing bilharzia infection contains protein — Carcinoid Tumour of the Ileum with Metastases by C E Dukes and P. Lockhart-Mummery (London) The basal-celled cancers of the ileo-cæcal region seldom give rise to secondary growths which in this case were found in the peritoneum, liver, and regional lymph glands —The Influence of Locally Injected Indian Ink on the Intracutaneous Response to Vaccinia and Other Viruses, by J C G Ledingham (London). Occupation of the reticulo-endothelial system by Indian ink much diminishes or prevents the local reaction to vaccinia virus, streptococci, and diphtheria toxin —A Combination of Bismuth and Sodium Sulphite Affording an Enrichment and Selective Medium for the Typhoid-paratyphoid Groups of Bacteria, by W J Wilson and E M M'V Blair (Belfast) Another of Prof Wilson's useful pieces of technique —Proceedings of the Thirty-third Meeting of the Society —Lamb Dysentery, by T Dalling (London) The disease, in places where it generally kills 20–30 per cent of the new-born lambs, may be almost entirely prevented by dosing the lambs with a mixture of *coli* and *welchii* antisera or, more conveniently, by immunising the pregnant ewes with *coli* vaccine and a *welchii* toxin-antitoxin mixture — Aminostyryl Quinoline and Aminoanil Quinoline Compounds, by C H Browning, J B Cohen, S Ellingworth, and R Gulbransen (Glasgow and Leeds) These new trypanocidal agents have a powerful curative effect on mice and rabbits infected with *T brucei*, they are not suitable for intravenous injection —The Different Immunising Values of Vaccines Made with Smooth and Rough Forms of Bacteria, by J A Arkwright (London) The smooth form of paratyphoid A is more virulent and makes a better vaccine than the rough form —The Value of Taurine for Promoting the Growth of the Gonococcus, by J Gordon (Leeds) The effect is attributed to a lowering of surface tension and a concentration of the taurine on the surfaces of the bacilli —Immunity Produced by the Schick Test, by R A O'Brien (London) The minute doses of diphtheria toxin used in Schick tests are capable of rousing an active immunity.—The Histological Criteria of Ulcer-Cancer of the Stomach, by M J Stewart (Leeds) The important evidence of chronic ulceration is destruction of the muscular coat, the pitfall in the diagnosis of carcinoma is the misinterpretation of misplaced epithelium which is much more common in the stomach than is supposed Of 260 stomachs removed surgically, 163 showed simple chronic ulcer, 80 cancer only, and 17 both

Reports and Analytical Records.

RYVITA CRISP BREAD (MIXED)

(THE RYVITA CO, 96, SOUTHWARK-STREET, S E 1)

THIS crisp bread (Knäckerbrod), imported from Sweden, is prepared from crushed whole rye The perforated crisp bread is made up in the form of rectangular biscuits, 4 in by 2½ in by ⅛ in, which are very palatable, especially if eaten with butter There is more character in the flavour of rye than in wheat, and the food value of the former needs no comment

The crisp bread is sold in two forms, light and dark, the latter presumably being more heavily baked On analysis the following results were obtained —

	Light crisp bread, per cent.	Dark crisp bread, per cent
Carbohydrates, altered starch, hemicellulose, &c	74 8	73 6
Protein	11 6	12 6
Moisture	9 0	9 3
Ash	1 8	2 1
Fat	1 3	1 0
Fibre	1 5	1 4
Calorie value per lb	1662	1613

Ryvita crisp bread, which keeps well and does not readily become 'slack,' is easily masticated and digested, and is a useful and palatable addition to the diet. The calorie value shows it to be a concentrated form of food

Annotations.

"Ne quid nimis"

SCHOOL-BOY DIET

THE science of dietetics, even allowing for the impetus given by the new knowledge of accessory food factors, has not kept pace with recent advance in other branches of medicine Practically all the dietaries in use at institutions and large communal centres no less than in individual homes when feeding is not simply haphazard are based on standards hallowed by custom alone and based on unproven or insufficient data Few observations in the literature of nutrition are comparable in experimental validity with Dr Corry Mann's report just issued[1] by the Medical Research Council While the importance of milk as an item in the diet of children has long been widely recognised, it is nevertheless startling to learn that the addition of one pint of milk a day to a diet which by itself satisfied the appetite of growing boys could convert an average annual gain of weight of 3 85 lb per boy into one of 6 98 lb per boy, and an average increase of height from 1 84 inches per boy to 2 63 inches per boy, and that coincident with this striking increase in weight and height the boys were obviously more fit than those in the other groups" The investigation was carried out during the four years beginning December, 1921, at a colony of some 500 boys housed in a model settlement of the villa type, with 30 to 35 boys in each house The conditions for a controlled experiment were ideal The institution is situated in a healthy spot some eleven miles from London Sleeping and living accommodation are excellent, as well as the control and discipline of the boys Three weeks' leave of absence are allowed in August and 10 days at Christmas, but only a few of the boys availed themselves of it, so that for the most part there was no break in the observations upon nutrition and growth during a considerable period of the school age, amounting in some cases to a continuous residence of four years without any disturbing social or environmental factor The boys, who are all of foundling type from the South of England were examined to exclude the possibility of latent or active disease and were graded A1 to B3, equal numbers of the same age and grade being assigned as far as possible to the various houses A preliminary observation from December, 1921, till March, 1922, was maintained upon the boys in order to demonstrate that, among other things, the basic diet was of adequate physiological value, which is defined in the report as "one which provides the necessary energy for basal metabolism and excretion loss besides additional calories for the minimum requirements of growth and activity"

The report sets out in its entirety the daily basal diet of the boys with the daily and seasonal variations, the calorie value of each ingredient and each portion, and the relative proportions of proteins and fats (animal and vegetable) and carbohydrates The average number of calories per day per boy was 1916, each boy receiving protein, fat, and carbohydrate in the proportion of 13 18 68 Dr Mann suggests that while this distribution compares favourably with the dietary of working-class homes, a better proportion would be 15 35 50, Control of the basic diet was maintained by weighing maximum and minimum samples at the table, disregarding the total amounts issued from store The samples taken were then subjected to skilled analysis Sixty-one boys who received only the basic diet of the village gained an average of 3 85 lb per boy and grew an average of 1 84 inches per boy during 12 months, and these average increments were maintained in 38 boys who remained under observation for two years Mere increase in weight and height was not considered enough to establish the existence of good general health, but full clinical examinations were systematically made on each boy On these findings the basic diet appeared to be of adequate calorie value for the control of the diet was intimate, individual idiosyncrasy becoming negligible when dealing with such numbers, and the length of the investigation levelling any seasonal variation The object of the research was how to discover whether increase in height and weight could be obtained best by giving extra calories e g by adding sugar or fat, or by giving fat with vitamin, or by giving vitamin alone or whether the biological value of the diet could be readily enhanced by giving an additional ration of animal protein or by giving milk which supplies so many factors in an easily assimilable form Forty-one boys received a ration extra to the basal diet of 1 pint (388 calories) of fresh cow's milk—pasteurised and homogenised, and these boys gained an average of 6 98 lb per boy and grew an average of 2 63 inches per boy in 12 months Twenty-three boys who were under observation for two years gained an average of 13 17 lb per boy and gained in height an average of 5 21 inches per boy It is remarked that these boys could be picked out by a casual visitor as being so obviously more generally fit and there was a complete absence of illness among them during a period when in the other houses there was a higher sick-rate than usual Twenty boys received a daily addition of 3 oz of castor sugar (350 calories), and gained an average of 4 93 lb per boy, and grew an average of 1 91 inches per boy in 12 months Twenty-six boys received an additional ration of 1¾ oz of grass fed New Zealand butter (387 calories)—this butter had a uniformly high vitamin A content as tested on rats by Dr K H Coward in University College, these boys gained an average of 6 30 lb per boy, and grew an average of 2 22 inches per boy in 12 months Sixteen boys received an additional ration of 1¾ oz of vegetable margarine (379 calories)—Dr Coward reports that rats required ten times the amount of this vitamin deficient margarine to produce results comparable with New Zealand butter, these boys gained an average of 5 21 lb per boy, and grew an average of 1 84 inches per boy in 12 months Thirty boys received ¾ oz of edible casein (65 calories) as an additional ration—this approximately doubled the amount of animal protein in the basic diet—they gained an average of 4 01 lb per boy, and grew an average of 1 76 inches per boy Twenty-six boys received in addition to the basic diet ¾ oz of fresh watercress, they gained an average of 5 42 lb per boy and grew an average of 1 70 inches per boy in 12 months

Dr M Greenwood and Miss E M Newbold have statistically analysed these results and they state that "the general concordance of the results in the different groups inspires confidence in their stability in spite of the small numbers in some of the subgroups" They conclude that "the milk and butter groups both show definite excess increase in weight over the basic group, and of the same order but slightly higher for the milk group . the milk group shows a definite excess growth in height over the basic group the excess growth of the butter group over the basic is not significant and is only one-third that of the milk group" This eminently practical research clearly shows that an accepted diet was deficient in full biological value The striking result obtained was not due to the relatively small increase in calorie value, but to the specific qualities of milk as a food, and while we can await with patience the decision as to what precise factors caused this result, the immediate lesson to be drawn from the report is the necessity for finding trustworthy standards of growth and nutrition anæsthesia may be found advisable for the sake of diminishing operative shock, or by means of splanchnic anæsthesia In this the region of the semilunar ganglia is infiltrated with novocaine before operation from behind by the method of Kappis, or after the abdomen has been opened by the method of Braun The former, which has obvious advantages, has already been tested by English, French, and American surgeons, whilst in Vienna Prof FINSTERER has an experience of each method in over 800 cases The statistics which he presented were sufficient proof of the brilliant results obtained, including as they did many operations of the first magnitude, carried through without the use of general anæsthesia One complicated gastrectomy occupied five hours, at the end of which time the patient left the theatre carrying on a lively discussion with the surgeon Continuous observation of the blood pressure is a useful criterion by which to determine the continuance of any operation, the pulse-rate being taken into account at the same time, a point which was emphasised in the discussion by Dr C W MOOTS, of Toledo, U S A, who was also a strong advocate of nitrous oxide While the audience was greatly impressed by the Vienna experience, it will take much persuasion to convince surgeons in this country that the final word is not with the combined methods which relieve both patient and surgeon of the anxieties of having a conscious subject, and which abolish at the same time those afferent impulses which CRILE and other workers have shown to play such an important part in the production of surgical shock Nitrous oxide inhalation combined with splanchnic or parasacral injections should enable any abdominal operation to be carried out with safety and convenience, especially if the rectus muscle is infiltrated at the commencement The experience of those who have used the combined methods points to a facility in technique for the operator, a degree of safety for the patient, and an absence of later complications, such as is unknown with the older methods even in the most skilled hands The newer methods, however, involve a coördination between surgeon and anæsthetist, which can only be reached by long practice The Nottingham discussion will do much to make this coördination more common than it is at present

FOOT-AND-MOUTH DISEASE INFECTION.

A FARMER was fined £15 at Crewe on July 2nd for allowing foreign meat wrappings to come in contact with the live-stock on his farm This was an offence against the Foot-and-Mouth Disease (Packing Materials) Order made last November Clause 2 of the Order enacts that no cloth, wrapping, sacking, or other material which has been used for the wrapping of meat, meat products, offals, or other parts of a carcass shall be brought into contact with any animal in Great Britain unless and until it has been boiled or otherwise thoroughly sterilised after being so used The maximum penalty is a fine of £20 An outbreak of foot-and-mouth disease occurred at the defendant's farm, and an inspector of the Ministry of Agriculture who visited him discovered that the farmer also kept a grocery business in Crewe and had bought large quantities of bacon from Denmark, Poland, and Holland The wrappings from these bales of bacon were taken from his grocery establishment and placed in an open shed on the farm to which his pigs had access He had also mixed imported bacon with the pig's food It was further stated at the police-court that, after the outbreak on the defendant's farm, cattle on an adjoining farm contracted the disease A few days later there was a third outbreak, involving the slaughter of 119 head of cattle, and the defendant admitted he had lent some harness to the farmer who owned these animals

A question about this prosecution was addressed on July 8th to the Minister of Agriculture in the House of Commons, Mr W THORNE asking whether the Minister was aware of the case and whether he would undertake to revise the existing prohibition so as to make it applicable only in reference to bacon imported in wrappings and pigs with hair on Mr GUINNESS, in his reply, explained the object of the Order Foreign meat and bacon may itself be free from disease, but, because it is packed in places where live animals are received, the wrappings may become contaminated after the meat is packed. The Minister went on to say that, if the Order had been obeyed in the Crewe case, it was possible that that particular outbreak would never have occurred He therefore saw no reason to modify the existing prohibition on the entry of fresh carcasses into this country from the continent He added that he intended to give the widest publicity to the Crewe conviction in order to call the attention of stock-owners to the Order, and the course thus pursued is commendable and even necessary when the grave trouble and expense to the community are remembered which follow the occurrence and repression of this pestilence On July 12th Mr THORNE asked the further question whether, before issuing a general embargo against pork imports from the Continent, any inquiry was held as to the possibility of distinguishing between pork as imported for the last three years to the London meat market and pigs unscalded and unscraped, such as were alleged to have caused foot and-mouth disease in Scotland. The Minister replied that scalding and scraping of a pork pig does not destroy the virus; the scraping off of the epidermis which follows the scalding merely makes the disease more difficult to detect

It may be mentioned that the defendant and his wife were also fined £1 for using a public footpath which had been closed in consequence of the outbreak This penalty shows what unusual measures have been required and have been taken in order to restrict the spread of foot-and-mouth disease Under Clause 8 of the Foot-and-Mouth Disease (Infected Areas) Order of 1924 an inspector of the Ministry or of the local authority can prohibit entry into a field, shed, or other place in an "infected area" notwithstanding the existence of any footpath or right of way Doubtless a good deal of publicity will be required in agricultural communities if such regulations are to be observed and enforced

PROFESSOR TEISSIER

WE are happy to correct the error made by one of our Paris correspondents in announcing the death of Prof Teissier, medical chief of the Claude Bernard Hospital in Paris Prof Pierre-Joseph Teissier is, on his own showing, alive and active in his devotion to the study and teaching of the nature of infectious disease The incorrect report was based upon a confusion of his name with that of his late uncle, Prof Louis-Joseph Teissier, of Lyon, and we may express the hope that the distinguished nephew, who is still in the prime of life, has many years before him to continue the bedside demonstrations which form so useful a part in the education of French students of medicine.

come to his notice in Aberdeen and emphasised the difficulty of being sure whether some of the tumours were sarcomata or carcinomata. In the past it has been too readily assumed that the majority at any rate arose from connective tissue, and Mr. W. G. Barnard's examination of a series from University College Hospital communicated to the July issue of the *Journal of Pathology and Bacteriology* noticed in another part of our present issue throws substantial doubt on this assumption. He divides the large tumours of the mediastinum growing in the hilum of the lung and in the bronchial glands into three histological groups: (1) squamous-celled epithelioma; (2) polygonal spheroidal or cubical-celled carcinoma sometimes mucus-secreting; (3) the tumours which have been known as "oat-celled sarcoma." The first group may with experience be distinguished naked eye, but between the second and third there is no constant gross difference. Moreover, if the oat-celled tumours are examined more thoroughly they will be found in places to present a cellular structure suggestive if not demonstrative of an epithelial origin. The bulk is composed of oval cells which would naturally be called sarcoma, but these are sometimes arranged in rows and in parts are distinctly polygonal and may form definite cubical epithelium lining tubules or attempts at tubules. In Mr. Barnard's view therefore these oat-celled tumours are carcinomata; they form the atypical end of a histological series which at the typical end is represented by columnar-celled mucous growths. One is reminded of the very sarcomatous appearance of parts of some of the epithelial tumours which have been produced by tar. The determination that the great majority of these mediastinal tumours arise in the lung rather than in the bronchial glands makes it perhaps more credible that influenza may be a precedent condition, though it has to be recognised that in pneumonia the regional lymphatic glands are probably not much less irritated than the lung itself.

TUBERCULOSIS AND PREGNANCY.

THERE are many old clinical sayings with regard to tuberculosis and pregnancy and, like proverbs, they often contradict each other. One school of the past taking a short view of the case believed that the outlook was improved by pregnancy and encouraged tuberculous girls to marry. Another laid it down in a dictum which has survived to the present day that a tuberculous woman bears the first pregnancy well and the second with difficulty, but that she rarely survives the third. Probably the confusion in thought on this question may be traced to the fact that there are at least three different points of view involved—namely, (1) the effect of pregnancy on tuberculosis, (2) the effect of tuberculosis on pregnancy, and (3) the effect of tuberculosis on the offspring. All these questions have been ventilated recently in different quarters. A discussion on the subject took place at the provincial meeting of the Tuberculosis Society in Cambridge[1] in March. Prof. Calmette's recent monograph[2] on tuberculosis in the new-born has summarised some of the results on the side of the offspring, and Dr. J. C. Litzenberg[3] has collected a number of records dealing with the statistical aspect. Obviously, much depends upon the material on which the reports are compiled. It is important to know whether the cases used for statistical purposes were sputum positive or sputum negative, what was the clinical character of the pulmonary disease before pregnancy took place, and finally data are required as to the environment of the patients and their opportunities for adequate anti-tuberculosis treatment.

With regard to the effect of pregnancy on tuberculosis modern clinical observations seem to show that the tuberculous woman does well during pregnancy, but is exposed to grave risks of relapse immediately after the confinement. In the discussion which took place at Cambridge, several speakers emphasised this view and stated that in their opinion patients who were able to avail themselves of adequate sanatorium treatment passed through the months of pregnancy exceptionally well. The other side of the picture is emphasised by those who have to treat tuberculosis and pregnancy in the out-patient class of woman, who by reason of economic circumstances and family cares are unable to adapt their way of life to the cure of the tuberculosis. The risks of recrudescence of tuberculosis in pregnancy are clearly not due to the mere mechanical factors associated with the enlargement of the uterus, and in the discussion at Cambridge Dr. Geoffrey Marshall suggested that some biochemical factor might well lie at the root of the difficulty. Metabolism is profoundly altered in pregnancy, and tuberculosis cannot but be complicated by the adjustments which the body has to make. As to the effect of tuberculosis on pregnancy, this is often surprisingly slight. In the article quoted above, Dr. Litzenberg states that tuberculosis does not appear to predispose the patient to the risks of abortion, but, nevertheless, his figures show that 7–10 per cent. of babies born of tuberculous mothers are still-born, and that 12–13 per cent. die in the puerperium. In view of the various risks involved the question arises whether or not the pregnancy should be interrupted. In Dr. Litzenberg's experience interruption during the first three months has not given good results and he is in favour of taking the chances of allowing the pregnancy to continue its natural course. He does not, however, discuss the question as to whether interference is necessary at or near the end of the pregnancy. The majority of the speakers at Cambridge stated that in their experience the tuberculous woman passed through the time of confinement exceptionally well and that the fœtus, usually small, gave rise to no mechanical difficulties for the obstetrician. In any case the parents and the physician must face the question as to whether or not the mother should be allowed to take the risks of a second pregnancy and, if not, what measures should be taken to eliminate this risk. Apparently there are wide differences of opinion. On the one hand the view is held that in serious cases pregnancy terminated by Cæsarean section with sterilisation effected at the same operation is the safest course, others adopt the easy practice of 'leaving matters to Nature.' Between these two extremes are various intermediate courses such as sterilisation by means of X rays which is said to last only for some four years, and the more obvious methods of contraception. Probably most physicians would at any rate agree that a second pregnancy should not follow until the tuberculous lesion has remained quiescent for a period of two years. Finally, there is the child to consider. Prof. Calmette has collected a number of sets of statistics dealing with the mortality from tuberculosis amongst infants born of tuberculous mothers. These figures appear to vary within very wide limits in different countries. According to Calmette, Prof. Forssner, of Stockholm, states that 70 out of 100 children born of tuberculous mothers and brought up in their tuberculous environment die before the age of 12 months, while Lissant Cox and MacNalty[4] put the figure at 22 per cent. for one dispensary in Great Britain. In France, Prof. Calmette estimates that 25 per cent. of such children die before they are a year old. It is clear that the risk to the child of having been born of a tuberculous mother is grave and no doubt this risk was in times past the main argument in favour of the hereditary nature of tuberculosis. There is abundant evidence nowadays to show that it is not a question of heredity but of close and intimate contact with an infective focus during the first few months of life.

It would appear to be impossible to lay down any very definite rules as to the treatment of a tuberculous woman who is or may become pregnant. In many cases there would seem to be no reason for terminating

SPINAL AND PERIPHERAL FORMS OF EPIDEMIC ENCEPHALOMYELITIS

SOON after epidemic encephalitis became recognised, the suggestion was put forward that certain cases of myelitis and even of polyneuritis should also be attributed to the same virus. Such cases are not common, however, and when the signs of encephalitis have not been definite the attitude of physicians in this country towards the ætiology has generally been one of cautious agnosticism. Abroad, and particularly in France, a relationship has been more freely acknowledged, and Cruchet and Verger[1] now claim to have encountered in their own experience no less than 39 cases of myelitis, radiculitis, or polyneuritis which they regard as anatomically inferior forms of the same disease. Of these, 28 were cases of myelitis, and the authors divide them into four groups according to whether the symptoms indicated that the spinal infection was anterior, lateral, posterior, or diffuse. The first group closely resembles the commoner acute anterior poliomyelitis, but may be accompanied at the onset by somnolence and diplopia. The spines corresponding to the inflamed segments of the cord may be tender, pain in the affected limbs is the rule, as in poliomyelitis in the adult and muscular atrophy sets in rapidly, the muscular affection may at first be widespread, but there is a tendency to gradual recovery, and after a few months cure of the paralysis may be almost complete, the cerebro-spinal fluid may be normal or may show an increase in its sugar content and a slight lymphocytosis. The lateral or spastic type may for a time resemble amyotrophic lateral sclerosis, but unlike that disease, it has the same tendency to regression as is seen in the anterior group. The posterior type resembles an acute tabes. There are lightning pains, feelings of constriction, sensory changes, sphincter paralysis, and great incoordination in all limbs, but the pupils preserve their reaction to light, the Wassermann reaction is negative and the sugar content of the cerebro-spinal fluid is increased, in some cases transitory diplopia attends the onset, the course is usually towards recovery, but involvement of the bulb may cause death in the acute stage. The diffuse cases share the features of the other three groups and are characterised by remarkable transformation in their symptoms during the evolution of the disease. One case, diagnosed at the beginning as polyneuritis, became spastic nearly a year later and finally recovered, in the cerebro-spinal fluid the sugar was increased, the Wassermann reaction was negative, and there were 2–3 lymphocytes per c.mm. Other cases resemble the better-known forms of transverse myelitis, but have a greater tendency to recovery; the symptoms, even when there is complete flaccid paraplegia, may completely disappear after six months or more. The cases diagnosed as nerve-root inflammation or radiculitis numbered six. They were characterised by persistent dull shooting pains brought on by effort, or by coughing, sneezing and the like, and usually believed to be caused by muscular rheumatism. The symptoms ceased after six or eight weeks. In spite of vague ocular disturbances at the beginning in a few, the evidence of encephalitic infection in these cases is extremely slender. Five cases of polyneuritis were ascribed to the same infection, but Cruchet and Verger themselves admit that it is very questionable whether the virus of encephalitis ever causes inflammation of the peripheral nerves, while sparing the central nervous system. In regard to polyneuritis and radiculitis the report does not carry conviction, in regard to myelitis, more might have been said of the evidence on which the supposition of identity of infection depends. A case of myelitis in which there is no clear evidence of another cause may be regarded as due to the infective agent of epidemic encephalitis if it occurs at a time when that disease is rife and if it is accompanied at the onset by somnolence and diplopia or has been recently preceded by these symptoms, the assumption is strengthened if the clinical picture produced differs materially from the usual pictures of acute anterior poliomyelitis and of transverse myelitis.

JOURNEES MÉDICALES DE PARIS

Journées Médicales are gatherings of doctors which differ from ordinary congresses in that they are for instruction rather than dispute. The idea originated in Belgium under Réné Beckers, and in Brussels 16 of these functions have taken place already, and their popularity is steadily increasing. In France they are also an established institution and Journées Médicales were held at Toulouse in 1924 and 1925, as well as at Tunis and Casablanca. They have always been well attended, and it is not surprising that the idea has now been taken up in Paris, where there are immense resources of hospitality and where a large staff of teachers, both official and private, is available. The meeting held from July 15th to 19th, of which a brief account appears on page 303, was the first of its kind in the capital, and was opened by the President of the Republic in the presence of the Ministers of Education and Commerce and diplomatic representatives of many foreign powers. Its purpose was definitely utilitarian and practical, as was indicated by Prof. Widal, President of the Congress, in his opening address. The object of the Journees Médicales, he said, was to enable medical men to meet together from time to time and to gain as quickly as possible the teaching needed to bring their medical knowledge up to date. The progress of the last few years had been so rapid that only with difficulty could the practitioner keep himself in touch with the methods of investigation and of treatment which were continually transforming medical and surgical practice. Certainly the doctor had his books, he could read articles in the medical journals, and he could attend the discussions of learned societies, but how could he judge the value of so many different methods, and how could he recognise immediately the advantage to be drawn from them? This is a fair statement of the case for post-graduate education, and the Journées Médicales differ only from British post-graduate courses in the scale on which they are arranged. Conferences and demonstrations were held in many Parisian hospitals and laboratories in such a way as not to clash with one another in the time-table and as a complement to these lessons and lectures there was an exhibition at the Grand Palais where the practitioner might revise his knowledge of medical and surgical apparatus. Very many French doctors attended, but the gathering was especially remarkable for the large number of foreign medical men, some of whom took part in the demonstrations. Official delegates were sent from all parts of North and South America, and Spain, Italy, Portugal, Greece, Turkey, and China, as well as the Scandinavian countries and Holland, were well represented. The success of this memorable occasion will certainly encourage the medical faculty of Paris to repeat the undertaking.

MEDIASTINAL TUMOURS

MEDIASTINAL tumours are often difficult to diagnose during life and the pathologist may be equally in doubt about their precise nature later on. During the last two or three years a remarkable increase in their frequency has been noticed in America, Western Europe, and this country. The cause of this is not clear, if, as has been suggested, it is the influenza epidemic of 1918–19, their prevalence should presently subside to its former level and it will be of much interest to see what happens in the next few years. Meanwhile pathologists have had a much more ample supply of material and the essential character of some of the commoner forms has come under discussion again. At the last meeting of the Pathological Society of Great Britain and Ireland Prof. T. Shennan discussed critically the cases which had come to his notice in Aberdeen and emphasised the difficulty of being sure whether some of the tumours were sarcomata or carcinomata In the past it has been too readily assumed that the majority at any rate arise from connective tissue and Mr W G Barnard's examination of a series from University College Hospital, communicated to the July issue of the *Journal of Pathology and Bacteriology* noticed in another part of our present issue throws substantial doubt on this assumption He divides the large tumours of the mediastinum growing in the hilum of the lung and in the bronchial glands into three histological groups. (1) squamous celled epithelioma. (2) polygonal spheroidal or cubical-celled carcinoma, sometimes mucus secreting. (3) the tumours which have been known as "oat-celled sarcoma" The first group may with experience be distinguished naked eye but between the second and third there is no constant gross difference Moreover, if the oat-celled tumours are examined more thoroughly they will be found in places to present a cellular structure suggestive if not demonstrative of an epithelial origin The bulk is composed of oval cells which would naturally be called sarcoma but these are sometimes arranged in rows and in parts are distinctly polygonal and may form definite cubical epithelium lining tubules or attempts at tubules In Mr Barnard's view, therefore these oat-celled tumours are carcinomata they form the atypical end of a histological series which, at the typical end is represented by columnar-celled mucous growths. One is reminded of the very sarcomatous appearance of parts of some of the epithelial tumours which have been produced by tar The determination that the great majority of these mediastinal tumours arise in the lung rather than in the bronchial glands makes it perhaps more credible that influenza may be a precedent condition though it has to be recognised that in pneumonias the regional lymphatic glands are probably not much less irritated than the lung itself

TUBERCULOSIS AND PREGNANCY

THERE are many old clinical sayings with regard to tuberculosis and pregnancy and, like proverbs they often contradict each other. One school of the past taking a short view of the case believed that the outlook was improved by pregnancy and encouraged tuberculous girls to marry. Another laid it down in a dictum which has survived to the present day that a tuberculous woman bears the first pregnancy well and the second with difficulty, but that she rarely survives the third. Probably the confusion in thought on this question may be traced to the fact that there are at least three different points of view involved—namely (1) the effect of pregnancy on tuberculosis (2) the effect of tuberculosis on pregnancy, and (3) the effect of tuberculosis on the offspring All these questions have been ventilated recently in different quarters A discussion on the subject took place at the provincial meeting of the Tuberculosis Society in Cambridge[1] in March. Prof. Calmette's recent monograph[2] on tuberculosis in the new-born has summarised some of the results on the side of the offspring, and Dr. J C. Litzenberg[3] has collected a number of records dealing with the statistical aspect. Obviously, much depends upon the material on which the reports are compiled It is important to know whether the cases used for statistical purposes were sputum positive or sputum negative, what was the clinical character of the pulmonary disease before pregnancy took place, and finally data are required as to the environment of the patients and their opportunities for adequate anti-tuberculosis treatment.

With regard to the effect of pregnancy on tuberculosis modern clinical observations seem to show that the tuberculous woman does well during pregnancy but is exposed to grave risks of relapse immediately after the confinement In the discussion which took place at Cambridge, several speakers emphasised this view and stated that in their opinion patients who were able to avail themselves of adequate sanatorium treatment passed through the months of pregnancy exceptionally well The other side of the picture is emphasised by those who have to treat tuberculosis and pregnancy in the out-patient class of woman who by reason of economic circumstances and family cares are unable to adapt their way of life to the cure of the tuberculosis The risks of recrudescence of tuberculosis in pregnancy are clearly not due to the mere mechanical factors associated with the enlargement of the uterus and in the discussion at Cambridge Dr Geoffrey Marshall suggested that some biochemical factor might well lie at the root of the difficulty. Metabolism is profoundly altered in pregnancy, and tuberculosis cannot but be complicated by the adjustments which the body has to make As to the effect of tuberculosis on pregnancy, this is often surprisingly slight In the article quoted above, Dr. Litzenberg states that tuberculosis does not appear to predispose the patient to the risks of abortion but nevertheless his figures show that 7–10 per cent. of babies born of tuberculous mothers are still-born, and that 12–15 per cent. die in the puerperium In view of the various risks involved the question arises whether or not the pregnancy should be interrupted In Dr. Litzenberg's experience interruption during the first three months has not given good results and he is in favour of taking the chances of allowing the pregnancy to continue its natural course. He does not, however, discuss the question as to whether interference is necessary at or near the end of the pregnancy The majority of the speakers at Cambridge stated that in their experience the tuberculous woman passed through the time of confinement exceptionally well and that the fœtus usually small, gave rise to no mechanical difficulties for the obstetrician. In any case, the parents and the physician must face the question as to whether or not the mother should be allowed to take the risks of a second pregnancy and, if not what measures should be taken to eliminate this risk. Apparently there are wide differences of opinion On the one hand the view is held that in serious cases pregnancy terminated by Cæsarean section with sterilisation effected at the same operation is the safest course, others adopt the easy practice of 'leaving matters to Nature.' Between these two extremes are various intermediate courses, such as sterilisation by means of X rays which is said to last only for some four years, and the more obvious methods of contraception Probably most physicians would at any rate agree that a second pregnancy should not follow until the tuberculous lesion has remained quiescent for a period of two years. Finally, there is the child to consider. Prof Calmette has collected a number of sets of statistics dealing with the mortality from tuberculosis amongst infants born of tuberculous mothers. These figures appear to vary within very wide limits in different countries. According to Calmette, Prof. Forssner, of Stockholm, states that 70 out of 100 children born of tuberculous mothers and brought up in their tuberculous environment die before the age of 12 months while Lissant Cox and MacNalty[4] put the figure at 22 per cent for one dispensary in Great Britain In France, Prof. Calmette estimates that 25 per cent of such children die before they are a year old It is clear that the risk to the child of having been born of a tuberculous mother is grave and no doubt this risk was in times past the main argument in favour of the hereditary nature of tuberculosis. There is abundant evidence nowadays to show that it is not a question of heredity but of close and intimate contact with an infective focus during the first few months of life.

It would appear to be impossible to lay down any very definite rules as to the treatment of a tuberculous woman who is or may become, pregnant In many cases there would seem to be no reason for terminating

SPINAL AND PERIPHERAL FORMS OF EPIDEMIC ENCEPHALOMYELITIS

Soon after epidemic encephalitis became recognised, the suggestion was put forward that certain cases of myelitis and even of polyneuritis should also be attributed to the same virus Such cases are not common, however, and when the signs of encephalitis have not been definite the attitude of physicians in this country towards the ætiology has generally been one of cautious agnosticism Abroad, and particularly in France, a relationship has been more freely acknowledged, and Cruchet and Verger[1] now claim to have encountered in their own experience no less than 39 cases of myelitis, radiculitis, or polyneuritis which they regard as anatomically inferior forms of the same disease Of these, 28 were cases of myelitis, and the authors divide them into four groups according to whether the symptoms indicated that the spinal infection was anterior, lateral, posterior, or diffuse The first group closely resembles the commoner acute anterior poliomyelitis, but may be accompanied at the onset by somnolence and diplopia The spines corresponding to the inflamed segments of the cord may be tender, pain in the affected limbs is the rule, as in poliomyelitis in the adult and muscular atrophy sets in rapidly, the muscular affection may at first be widespread, but there is a tendency to gradual recovery, and after a few months cure of the paralysis may be almost complete, the cerebro-spinal fluid may be normal or may show an increase in its sugar content and a slight lymphocytosis The lateral or spastic type may for a time resemble amyotrophic lateral sclerosis, but unlike that disease, it has the same tendency to regression as is seen in the anterior group The posterior type resembles an acute tabes There are lightning pains, feelings of constriction, sensory changes, sphincter paralysis, and great incoordination in all limbs, but the pupils preserve their reaction to light, the Wassermann reaction is negative and the sugar content of the cerebro-spinal fluid is increased, in some cases transitory diplopia attends the onset, the course is usually towards recovery, but involvement of the bulb may cause death in the acute stage The diffuse cases share the features of the other three groups and are characterised by remarkable transformation in their symptoms during the evolution of the disease One case, diagnosed at the beginning as polyneuritis, became spastic nearly a year later and finally recovered, in the cerebro-spinal fluid the sugar was increased, the Wassermann reaction was negative, and there were 2–3 lymphocytes per c mm Other cases resemble the better-known forms of transverse myelitis, but have a greater tendency to recovery, the symptoms, even when there is complete flaccid paraplegia, may completely disappear after six months or more The cases diagnosed as nerve-root inflammation or radiculitis numbered six. They were characterised by persistent dull shooting pains brought on by effort, or by coughing, sneezing and the like, and usually believed to be caused by muscular rheumatism The symptoms ceased after six or eight weeks In spite of vague ocular disturbances at the beginning in a few, the evidence of encephalitic infection in these cases is extremely slender Five cases of polyneuritis were ascribed to the same infection, but Cruchet and Verger themselves admit that it is very questionable whether the virus of encephalitis ever causes inflammation of the peripheral nerves, while sparing the central nervous system In regard to polyneuritis and radiculitis, the report does not carry conviction, in regard to myelitis, more might have been said of the evidence on which the supposition of identity of infection depends A case of myelitis in which there is no clear evidence of another cause may be regarded as due to the infective agent of epidemic encephalitis if it occurs at a time when that disease is rife and if it is accompanied at the onset by somnolence and diplopia or has been recently preceded by these symptoms, the assumption is strengthened if the clinical picture produced differs materially from the usual pictures of acute anterior poliomyelitis and of transverse myelitis

JOURNÉES MÉDICALES DE PARIS

Journées Médicales are gatherings of doctors which differ from ordinary congresses in that they are for instruction rather than dispute The idea originated in Belgium under Réné Beckers, and in Brussels 16 of these functions have taken place already, and their popularity is steadily increasing In France they are also an established institution and Journées Médicales were held at Toulouse in 1924 and 1925, as well as at Tunis and Casablanca They have always been well attended, and it is not surprising that the idea has now been taken up in Paris, where there are immense resources of hospitality and where a large staff of teachers, both official and private, is available The meeting held from July 15th to 19th, of which a brief account appears on page 303, was the first of its kind in the capital, and was opened by the President of the Republic in the presence of the Ministers of Education and Commerce and diplomatic representatives of many foreign powers Its purpose was definitely utilitarian and practical, as was indicated by Prof. Widal, President of the Congress, in his opening address The object of the Journées Médicales, he said, was to enable medical men to meet together from time to time and to gain as quickly as possible the teaching needed to bring their medical knowledge up to date The progress of the last few years had been so rapid that only with difficulty could the practitioner keep himself in touch with the methods of investigation and of treatment which were continually transforming medical and surgical practice Certainly the doctor had his books, he could read articles in the medical journals, and he could attend the discussions of learned societies, but how could he judge the value of so many different methods, and how could he recognise immediately the advantage to be drawn from them ? This is a fair statement of the case for post-graduate education, and the Journées Médicales differ only from British post-graduate courses in the scale on which they are arranged Conferences and demonstrations were held in many Parisian hospitals and laboratories in such a way as not to clash with one another in the time-table, and as a complement to these lessons and lectures there was an exhibition at the Grand Palais where the practitioner might revise his knowledge of medical and surgical apparatus Very many French doctors attended, but the gathering was especially remarkable for the large number of foreign medical men, some of whom took part in the demonstrations Official delegates were sent from all parts of North and South America, and Spain, Italy, Portugal, Greece. Turkey, and China, as well as the Scandinavian countries and Holland, were well represented The success of this memorable occasion will certainly encourage the medical faculty of Paris to repeat the undertaking

MEDIASTINAL TUMOURS

Mediastinal tumours are often difficult to diagnose during life and the pathologist may be equally in doubt about their precise nature later on During the last two or three years a remarkable increase in their frequency has been noticed in America, Western Europe, and this country The cause of this is not clear, if, as has been suggested, it is the influenza epidemic of 1918–19, their prevalence should presently subside to its former level and it will be of much interest to see what happens in the next few years Meanwhile pathologists have had a much more ample supply of material and the essential character of some of the commoner forms has come under discussion again At the last meeting of the Pathological Society of Great Britain and Ireland Prof T Shennan discussed critically the cases which had come to his notice in Aberdeen and emphasised the difficulty of being sure whether some of the tumours were sarcomata or carcinomata. In the past it has been too readily assumed that the majority of them originate from connective tissue, and Mr W. G. Barnard's examination of a series from University College Hospital communicated to the July issue of the *Journal of Pathology and Bacteriology* (noticed in another part of our present issue) throws substantial doubt on this assumption. He divides the large tumours of the mediastinum growing in the hilum of the lung and in the bronchial glands into three histological groups: (1) squamous-celled epithelioma; (2) polygonal spheroidal or cubical-celled carcinoma sometimes mucus secreting; (3) the tumours which have been known as "oat-celled sarcoma." The first group may with experience be distinguished naked eye, but between the second and third there is no constant gross difference. Moreover if the oat-celled tumours are examined more thoroughly they will be found in places to present a cellular structure suggestive if not demonstrative of an epithelial origin. The bulk is composed of oval cells which would naturally be called sarcoma but these are sometimes arranged in rows and in parts are distinctly polygonal and may form definite cubical epithelium lining tubules or attempts at tubules. In Mr Barnard's view, therefore these oat-celled tumours are carcinomata; they form the atypical end of a histological series which at the typical end is represented by columnar-celled mucous growths. One is reminded of the very sarcomatous appearance of parts of some of the epithelial tumours which have been produced by tar. The determination that the great majority of these mediastinal tumours arise in the lung rather than in the bronchial glands makes it, perhaps, more credible that influenza may be a precedent condition, though it has to be recognised that in pneumonias the regional lymphatic glands are probably not much less irritated than the lung itself.

TUBERCULOSIS AND PREGNANCY.

THERE are many old clinical sayings with regard to tuberculosis and pregnancy and, like proverbs, they often contradict each other. One school of the past taking a short view of the case believed that the outlook was improved by pregnancy and encouraged tuberculous girls to marry. Another laid it down in a dictum which has survived to the present day that a tuberculous woman bears the first pregnancy well and the second with difficulty, but that she rarely survives the third. Probably the confusion in thought on this question may be traced to the fact that there are at least three different points of view involved—namely, (1) the effect of pregnancy on tuberculosis, (2) the effect of tuberculosis on pregnancy, and (3) the effect of tuberculosis on the offspring. All these questions have been ventilated recently in different quarters. A discussion on the subject took place at the provincial meeting of the Tuberculosis Society in Cambridge[1] in March. Prof. Calmette's recent monograph[2] on tuberculosis in the new-born has summarised some of the results on the side of the offspring and Dr. J. C. Litzenberg[3] has collected a number of records dealing with the statistical aspect. Obviously, much depends upon the material on which the reports are compiled. It is important to know whether the cases used for statistical purposes were sputum positive or sputum negative, what was the clinical character of the pulmonary disease before pregnancy took place, and finally data are required as to the environment of the patients and their opportunities for adequate anti-tuberculosis treatment.

With regard to the effect of pregnancy on tuberculosis, modern clinical observations seem to show that the tuberculous woman does well during pregnancy, but is exposed to grave risks of relapse immediately after the confinement. In the discussion which took place at Cambridge, several speakers emphasised this view and stated that in their opinion patients who were able to avail themselves of adequate sanatorium treatment passed through the months of pregnancy exceptionally well. The other side of the picture is emphasised by those who have to treat tuberculosis and pregnancy in the out-patient class of woman, who by reason of economic circumstances and family cares are unable to adapt their way of life to the cure of the tuberculosis. The risks of recrudescence of tuberculosis in pregnancy are clearly not due to the mere mechanical factors associated with the enlargement of the uterus and in the discussion at Cambridge Dr. Geoffrey Marshall suggested that some biochemical factor might well lie at the root of the difficulty. Metabolism is profoundly altered in pregnancy, and tuberculosis cannot but be complicated by the adjustments which the body has to make. As to the effect of tuberculosis on pregnancy, this is often surprisingly slight. In the article quoted above, Dr. Litzenberg states that tuberculosis does not appear to predispose the patient to the risks of abortion but, nevertheless, his figures show that 7–10 per cent. of babies born of tuberculous mothers are still-born, and that 12–15 per cent. die in the puerperium. In view of the various risks involved the question arises whether or not the pregnancy should be interrupted. In Dr. Litzenberg's experience interruption during the first three months has not given good results and he is in favour of taking the chances of allowing the pregnancy to continue its natural course. He does not, however, discuss the question as to whether interference is necessary at or near the end of the pregnancy. The majority of the speakers at Cambridge stated that in their experience the tuberculous woman passed through the time of confinement exceptionally well and that the fœtus, usually small, gave rise to no mechanical difficulties for the obstetrician. In any case, the parents and the physician must face the question as to whether or not the mother should be allowed to take the risks of a second pregnancy and, if not, what measures should be taken to eliminate this risk. Apparently there are wide differences of opinion. On the one hand, the view is held that in serious cases pregnancy terminated by Cæsarean section with sterilisation effected at the same operation is the safest course; others adopt the easy practice of "leaving matters to Nature." Between these two extremes are various intermediate courses such as sterilisation by means of X rays which is said to last only for some four years, and the more obvious methods of contraception. Probably most physicians would at any rate agree that a second pregnancy should not follow until the tuberculous lesion has remained quiescent for a period of two years. Finally, there is the child to consider. Prof. Calmette has collected a number of sets of statistics dealing with the mortality from tuberculosis amongst infants born of tuberculous mothers. These figures appear to vary within very wide limits in different countries. According to Calmette, Prof. Forssner, of Stockholm, states that 70 out of 100 children born of tuberculous mothers and brought up in their tuberculous environment die before the age of 12 months, while Lissant Cox and MacNalty[4] put the figure at 22 per cent. for one dispensary in Great Britain. In France, Prof. Calmette estimates that 25 per cent. of such children die before they are a year old. It is clear that the risk to the child of having been born of a tuberculous mother is grave, and no doubt this risk was in times past the main argument in favour of the hereditary nature of tuberculosis. There is abundant evidence nowadays to show that it is not a question of heredity but of close and intimate contact with an infective focus during the first few months of life.

It would appear to be impossible to lay down any very definite rules as to the treatment of a tuberculous woman who is, or may become, pregnant. In many cases there would seem to be no reason for terminating

JOURNÉES MÉDICALES DE PARIS

Journees Médicales are gatherings of doctors which differ from ordinary congresses in that they are for instruction rather than dispute The idea originated in Belgium under Réné Beckers, and in Brussels 16 of these functions have taken place already, and their popularity is steadily increasing In France they are also an established institution and Journées Medicales were held at Toulouse in 1924 and 1925, as well as at Tunis and Casablanca They have always been well attended, and it is not surprising that the idea has now been taken up in Paris, where there are immense resources of hospitality and where a large staff of teachers, both official and private, is available The meeting held from July 15th to 19th, of which a brief account appears on page 303, was the first of its kind in the capital, and was opened by the President of the Republic in the presence of the Ministers of Education and Commerce and diplomatic representatives of many foreign powers Its purpose was definitely utilitarian and practical, as was indicated by Prof. Widal, President of the Congress, in his opening address The object of the Journées Médicales, he said, was to enable medical men to meet together from time to time and to gain as quickly as possible the teaching needed to bring their medical knowledge up to date The progress of the last few years had been so rapid that only with difficulty could the practitioner keep himself in touch with the methods of investigation and of treatment which were continually transforming medical and surgical practice Certainly the doctor had his books, he could read articles in the medical journals, and he could attend the discussions of learned societies, but how could he judge the value of so many different methods, and how could he recognise immediately the advantage to be drawn from them? This is a fair statement of the case for post-graduate education, and the Journées Médicales differ only from British post-graduate courses in the scale on which they are arranged Conferences and demonstrations were held in many Parisian hospitals and laboratories in such a way as not to clash with one another in the time-table, and as a complement to these lessons and lectures there was an exhibition at the Grand Palais where the practitioner might revise his knowledge of medical and surgical apparatus Very many French doctors attended, but the gathering was especially remarkable for the large number of foreign medical men, some of whom took part in the demonstrations Official delegates were sent from all parts of North and South America, and Spain, Italy, Portugal, Greece, Turkey, and China, as well as the Scandinavian countries and Holland, were well represented The success of this memorable occasion will certainly encourage the medical faculty of Paris to repeat the undertaking

MEDIASTINAL TUMOURS

MEDIASTINAL tumours are often difficult to diagnose during life and the pathologist may be equally in doubt about their precise nature later on During the last two or three years a remarkable increase in their frequency has been noticed in America, Western Europe, and this country The cause of this is not clear, if, as has been suggested, it is the influenza epidemic of 1918–19, their prevalence should presently subside to its former level and it will be of much interest to see what happens in the next few years Meanwhile pathologists have had a much more ample supply of material and the essential character of some of the commoner forms has come under discussion again At the last meeting of the Pathological Society of Great Britain and Ireland Prof T Shennan discussed critically the cases which had come to his notice in Aberdeen and emphasised the difficulty of being sure whether some of the tumours were sarcomata or carcinomata. In the past it has been too readily assumed that the majority at any rate arise from connective tissue, and Mr W. G. Barnard's examination of a series from University College Hospital communicated to the July issue of the *Journal of Pathology and Bacteriology* noticed in another part of our present issue throws substantial doubt on this assumption. He divides the large tumours of the mediastinum growing in the hilum of the lung and in the bronchial glands into three histological groups: (1) squamous-celled epithelioma; (2) polygonal spheroidal or cubical-celled carcinoma, sometimes mucus secreting; (3) the tumours which have been known as "oat-celled sarcoma." The first group may with experience be distinguished naked eye, but between the second and third there is no constant gross difference. Moreover, if the oat-celled tumours are examined more thoroughly they will be found in places to present a cellular structure suggestive if not demonstrative of an epithelial origin. The bulk is composed of oval cells which would naturally be called sarcoma, but these are sometimes arranged in rows and in parts are distinctly polygonal and may form definite cubical epithelium lining tubules or attempts at tubules. In Mr Barnard's view, therefore, these oat-celled tumours are carcinomata; they form the atypical end of a histological series which at the typical end is represented by columnar-celled mucous growths. One is reminded of the very sarcomatous appearance of parts of some of the epithelial tumours which have been produced by tar. The determination that the great majority of these mediastinal tumours arise in the lung rather than in the bronchial glands makes it perhaps more credible that influenza may be a precedent condition, though it has to be recognised that in pneumonias the regional lymphatic glands are probably not much less irritated than the lung itself.

TUBERCULOSIS AND PREGNANCY.

THERE are many old clinical sayings with regard to tuberculosis and pregnancy and, like proverbs, they often contradict each other. One school of the past, taking a short view of the case, believed that the outlook was improved by pregnancy and encouraged tuberculous girls to marry. Another laid it down in a dictum which has survived to the present day that a tuberculous woman bears the first pregnancy well and the second with difficulty, but that she rarely survives the third. Probably the confusion in thought on this question may be traced to the fact that there are at least three different points of view involved—namely, (1) the effect of pregnancy on tuberculosis, (2) the effect of tuberculosis on pregnancy, and (3) the effect of tuberculosis on the offspring. All these questions have been ventilated recently in different quarters. A discussion on the subject took place at the provincial meeting of the Tuberculosis Society in Cambridge[1] in March. Prof. Calmette's recent monograph[2] on tuberculosis in the new-born has summarised some of the results on the side of the offspring, and Dr J. C. Litzenberg[3] has collected a number of records dealing with the statistical aspect. Obviously, much depends upon the material on which the reports are compiled. It is important to know whether the cases used for statistical purposes were sputum positive or sputum negative, what was the clinical character of the pulmonary disease before pregnancy took place, and finally data are required as to the environment of the patients and their opportunities for adequate anti-tuberculosis treatment.

With regard to the effect of pregnancy on tuberculosis, modern clinical observations seem to show that the tuberculous woman does well during pregnancy, but is exposed to grave risks of relapse immediately after the confinement. In the discussion which took place at Cambridge, several speakers emphasised this view and stated that in their opinion patients who were able to avail themselves of adequate sanatorium treatment passed through the months of pregnancy exceptionally well. The other side of the picture is emphasised by those who have to treat tuberculosis and pregnancy in the out-patient class of woman who by reason of economic circumstances and family cares are unable to adapt their way of life to the cure of the tuberculosis. The risks of recrudescence of tuberculosis in pregnancy are clearly not due to the mere mechanical factors associated with the enlargement of the uterus, and in the discussion at Cambridge Dr Geoffrey Marshall suggested that some biochemical factor might well lie at the root of the difficulty. Metabolism is profoundly altered in pregnancy, and tuberculosis cannot but be complicated by the adjustments which the body has to make. As to the effect of tuberculosis on pregnancy, this is often surprisingly slight. In the article quoted above, Dr Litzenberg states that tuberculosis does not appear to predispose the patient to the risks of abortion, but *nevertheless, his figures* show that 7–10 per cent. of babies born of tuberculous mothers are still-born, and that 12–15 per cent. die in the puerperium. In view of the various risks involved the question arises whether or not the pregnancy should be *interrupted*. In Dr Litzenberg's experience interruption during the first three months has not given good results and he is in favour of taking the chances of allowing the pregnancy to continue its natural course. He does not, however, discuss the question as to whether *interference* is necessary at or near the end of the pregnancy. The majority of the speakers at Cambridge stated that in their experience the tuberculous woman passed through the time of confinement exceptionally well and that the fœtus, usually small, gave rise to no mechanical difficulties for the obstetrician. In any case, the parents and the physician must face the question as to whether or not the mother should be allowed to take the risks of a second pregnancy and if not what measures should be taken to eliminate this risk. Apparently there are wide differences of opinion. On the one hand the view is held that in serious cases pregnancy terminated by *Cæsarean section* with sterilisation effected at the same operation is the safest course; others adopt the easy practice of 'leaving matters to Nature.' Between these two extremes are various intermediate courses such as sterilisation by means of X rays, which is said to last only for some four years, and the more obvious methods of contraception. Probably most physicians would at any rate agree that a second pregnancy should not follow until the tuberculous lesion has remained quiescent for a period of two years. Finally, there is the child to consider. Prof. Calmette has collected a number of sets of statistics dealing with the mortality from tuberculosis amongst infants born of tuberculous mothers. These figures appear to vary within very wide limits in different countries. According to Calmette, Prof. Forssner of Stockholm, states that 70 out of 100 children born of tuberculous mothers and brought up in their tuberculous environment die before the age of 12 months, while Lissant Cox and MacNalty[4] put the figure at 22 per cent. for one dispensary in Great Britain. In France Prof. Calmette estimates that 25 per cent. of such children die before they are a year old. It is clear that the risk to the child of having been born of a tuberculous mother is grave, and no doubt this risk was in times past the main argument in favour of the hereditary nature of tuberculosis. There is abundant evidence nowadays to show that it is not a question of heredity but of close and intimate contact with an infective focus during the first few months of life.

It would appear to be impossible to lay down any very definite rules as to the treatment of a tuberculous woman who is or may become pregnant. In many cases there would seem to be no reason for terminating the pregnancy until near the end of the nine months if at all, since the obstetric difficulties are usually no greater than in healthy women. The tuberculous woman, however, runs great risks of exacerbation of the tuberculous process all through the period of pregnancy and a still greater risk in the few months after the confinement is over, if the tuberculosis be not adequately treated. These risks can be greatly minimised by sanatorium régime and this institutional care would appear to be the obvious course of action in all patients whose circumstances will permit of it. The risks of second pregnancies must depend largely on the good sense of the parents and the wisdom of the physician in handling a difficult situation. For the infant the prospect is not a hopeful one. There is evidently a considerable risk of the infant dying of tuberculosis during the first year. This risk can no doubt be mitigated, if not entirely eliminated, in better-class homes where good nursing and adequate precautions against infection can be adopted. The treatment of tuberculosis is largely a financial question. Amongst the hospital classes pregnancy supervening upon tuberculosis is a grave danger and the outlook is gloomy. In the wealthier classes, where sanatorium treatment can be kept up for a long period and where the mother is not compelled to live in close contact with the infant from the moment of its birth, the outlook for both mother and child is obviously brighter.

THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE Museum of the Royal College of Surgeons is at present closed and will remain so for two months while Rooms I and II are being repainted. The Museum has not often been closed since access to it was made easy some years ago. It has not been in the decorators' hands for more than 20 years, when it was shut to the public, not having apparently been so closed since 1890 when the new Museum buildings were erected. We are so accustomed to the idea of the priceless Hunterian collection being accessible to all interested in its contents that it is at first not easy to realise the long periods in its early development when it was a kind of Bluebeard's chamber unknown to the general public and to many of our medical predecessors. A century ago the Museum was closed during at least eight months of the year, and visits thereto during the remaining four were often effected only by private arrangement with the conservator. It was an indefatigable member of the staff of THE LANCET, James Wardrop, of aneurysm fame, who first agitated in the cause of museum reform, though the conservator, William Clift, had already begun to conduct parties of visitors round the collection twice a day, a practice kept up by him to the end of his tenure of office. At the thirteenth meeting of a committee of members of the College, held at Freemasons' Tavern on July 7th, 1826, Wardrop presided and read to the assembled reformers the terms and conditions on which the Hunterian collection had been delivered to the College by Parliament. It was unanimously decided that the curators had not opened the Museum in the hours specified by the grant, while they had not prepared the catalogue in accordance with directions. It was thereupon proposed at the meeting, in view of the default of the authorities, that the Museum should be open for four hours every day (Sundays excepted) in the winter months and six hours in summer months, that it should be accessible to all suitable visitors, and that a catalogue should be compiled. The Museum Board of the College replied to this suggestion or rather stricture, by deciding that the Museum should be open two days a week for four hours at a time during the whole year. The movement for reform was therefore immediately successful up to a point, but it was not till 1865 that the collection came to be open at about the same times and hours as now. The accusation of neglect in providing a catalogue led to a full statement of excuses being presented to the Hunterian trustees apparently by Clift, the conservator, who had found John Hunter's collection in a state of chaos and had laboured for years to reduce it to order and to describe and identify particular specimens. The interesting history of the various printed editions of the catalogue will be found in the prefaces to Paget, Goodhart and Doran's "Descriptive Catalogue of the Pathological Specimens contained in the Museum of the Royal College of Surgeons," Edit. 2, 1882. These prefaces are an abundant justification of the old generation of conservators and a fine record of scientific progress. There is no doubt that the attitude of the Council of the College towards the members dictated a quite unreasonable and even illegal restriction of the members' rights in respect of the Hunterian Museum, but it is easy to see that the impossibility of an immediate preparation of a catalogue was not appreciated. The task was a very difficult one, and a misleading catalogue would have been worse than no catalogue at all.

FLUORESCENCE

IN the course of a series of articles[1] on the Pathological Action of Light upon the Eye, Dr. W. S. Duke-Elder stated that the wave length of fluorescent light was generally longer, but sometimes shorter than that of the exciting light. An annotation in our issue of July 3rd calling our readers' attention to the valuable way in which Dr. Duke-Elder had marshalled his facts for the benefit of the phototherapist contained the broad assertion that the wave-length of fluorescent light is never shorter than that of the exciting light. This is not strictly the case, for there is a very small group of bodies which under the excitation of light gives out radiation which is actually of shorter wave-length than that which excites it. These bodies constitute exceptions to Stokes's famous law, a law which has such wide application, not only in the luminous spectrum, but in the ultra-violet and X ray regions. While we gladly express our regret to Dr. Duke-Elder for having apparently controverted his perfectly correct statement, we would remind our readers that the bodies in question are at present puzzling exceptions to a law of wide validity. Full information about them is available in an article by Nichols and Merritt in the *Physical Review* (vols. xviii and xix.).

URETERAL AND TRIGONAL STRICTURE

MUCH of our knowledge of ureteral strictures has been derived from American observers, and A. H. Peacock and R. F. Hain have contributed further to this subject in the July number of *Surgery, Gynecology, and Obstetrics*. Their contribution consists of a study of 76 cases of ureteral stricture. In the ætiology of the condition the two chief factors are infection and trauma, of which the former is the more important, for out of 76 cases 63 gave a history of infection, either acute or chronic. The infection was not necessarily of the urinary tract; influenza, scarlet fever, diphtheria, pneumonia, puerperal fever, otitis media, and dental infection all led later to infection of the ureter. No preference was shown for either side, but the favourite site of the stricture was found to be the lower third, and in the case of women, more especially that portion of the ureter directly in relation to the broad ligament. The patients came under observation for a great variety of symptoms, many of them having been regarded as cases of neurasthenia. An interesting finding was the number of operations to which some of these patients had been subjected in order to obtain relief of their symptoms. One case, that of a woman of 28, who complained of frequency of micturition and tenesmus, and had once passed a small quantity of blood, had undergone two operations on the left hip, appendicectomy, salpingectomy, a partial oophorectomy, tonsillectomy an operation for intestinal adhesions, and a therapeutic abortion at the fifth month. The real source of her trouble was a ureteral stricture. In the majority of cases nothing beyond dilatation of the stricture by the passage of a ureteral bougie was found to be necessary.

[1] THE LANCET, June 12th, 19th, 26th, and July 3rd, 1926.

To the same journal Frank Hinman and Miley B. Wesson contribute an interesting article on the trigone of the bladder as a factor in urinary obstruction. It is, of course, well known that changes in the trigone occur in cases of urinary obstruction and infection. The authors lay emphasis on the fact that an hypertrophied interureteral ridge may from its form and position lead at times to obstructed urination. When this occurs surgical treatment may become necessary. This may take the form of incision of the ridge with suture and ligature of the incised ledges in order to control hæmorrhage or of resection of the ridge, and where necessary of the supratrigonal pouch so as to restore the base of the bladder to its normal form. The authors instance three cases under their care of urinary obstruction and infection in which the associated changes in the trigone were so marked that operative treatment was rendered necessary. In operating on a hypertrophied interureteral ridge care must be taken to avoid resecting so much of the trigonal muscle as to endanger its functional activity. Special precaution must also be taken against hæmorrhage, and for this reason Young's punch operation which otherwise might be regarded as suitable, should not be carried out. The article discusses the anatomy, physiology, and pathology of the trigone, of which our knowledge still remains meagre.

DE MOTU CORDIS

IT is the intention of the Royal College of Physicians of London to celebrate in 1928 the tercentenary of Harvey's publication of the famous treatise "*Exercitatio de Motu Cordis et Sanguinis*." It may be prophesied safely that the anniversary of Harvey's formal announcement of his grand discovery will be a marked date in all philosophical associations throughout the ages. That is a large prophecy, but the explanation of the circulation of the blood is, and always will be, recognised as the greatest physiological exploit the world has known. Harvey taught medicine to step in one gigantic stride from the tenets of the Alexandrian School to the medicine of the sixteenth century, behind which date we now need never look for the foundations of medical science. The poetical and classical allusions to the circulation of the blood were merely fanciful, even when their words may appear to imply exact knowledge. Galen's assistance in the final revelation should not be overlooked, for he pointed out that the arteries did contain blood as well as air, though he insisted that the septum between the right and left ventricles was permeable. Vesalius, three-quarters of a century before Harvey, demonstrated, though he did not assert, the complete separation of the ventricles, while just previously Sylvius had described the valves in the veins. The combined significance of the two researches was, however, missed, particularly as the valves were believed to act as brakes to the flow of blood from the heart. Servetus a little later, had a conception of the mass of the blood passing through the pulmonary artery and the lungs, but did not appreciate this lesser circuit as a part of a grand circulation of the whole. Harvey's treatise demonstrated the heart as the motor starting point of the blood placed the liver in its proper relations, and arrived at one general solution of the various problems in an incontrovertible manner, the only gap in his theory as it was first set out cannot be held as a reproach to him for the non-recognition of the capillary connexion between the arteries and the veins was due to his work being done without the assistance of the microscope. Malpighi completed the story of the circulation of the blood by the use of the newly invented microscope shortly after Harvey's death but Harvey's work had made Malpighi's addition a logical inference. The discovery was made and was promulgated in a faultless way. Before Harvey was ready with the exact demonstration he taught publicly in accordance with his theories, and although so radical a rearrangement of all physiology was not and could not be expected to be accepted universally and immediately, he had on his side throughout some of the greatest thinkers while others became rapid converts to his views. As is well known, there are competitors for the honour of discovering the circulation of the blood, but no one really familiar with the literature of the grounds upon which the claims are made can fail to see that William Harvey was the one and only revealer of the whole drama—the first man, indeed, who knew the plot.

A DIPLOMA IN NURSING

THE University of London has followed the University of Leeds in instituting a diploma in nursing and the first examinations will probably be held next year. The diploma is intended for those registered nurses who have undertaken further study and training so as to qualify for responsible posts, and it will generally be taken after a nurse has been qualified for at least two years, one of which must have been spent in a hospital or public health department. Before entering for the diploma the nurse will have to produce evidence of having attained to "a suitable standard of general education." The examination then required will be in two parts. The first may be taken at any time after registration or after the time at which the nurse becomes eligible to sit for the State examination, and for this part the candidate will have to show knowledge of the scientific basis and general principles of nursing, including elementary psychology, and of the history of nursing. When she has satisfied the examiners in this part the candidate may proceed to the second part, provided that for not less than two years she has been eligible to sit for the examination admitting to the general part of the Register of Nurses. In this part she need only offer one of the following alternative subjects: the nursing of children; mental nursing, including psychology, fever nursing and epidemiology, obstetric and gynæcological nursing; general nursing; or elementary economics, sociology and hygiene in relation to the duties of public health nurses or hospital administration. Those who enter for the first three of these subjects must for two years have been eligible to sit for the examination admitting to the appropriate supplementary part of the Register of Nurses. Those who take obstetrics and gynæcological nursing as their special subject must hold the certificate of the Central Midwives Board, whilst those who take elementary economics, sociology and hygiene must hold a health visitor's certificate. The examinations for the diploma will be held in October and November of each year and an elaborate syllabus is being published, together with a list of the books recommended to candidates. Registered nurses would be well advised to apply to the University of London for this syllabus and to the College of Nursing for information about existing post-graduate lectures. As a new objective the diploma will undoubtedly stimulate keen students, and its scope suggests that its effect on candidates will be educational as well as instructive.

INDEX TO "THE LANCET," VOL. I, 1926

THE Index and Title-page to Vol. I, 1926 which was completed with the issue of June 26th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET 1, Bedford-street Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

the pregnancy until near the end of the nine months if at all, since the obstetric difficulties are usually no greater than in healthy women The tuberculous woman, however, runs great risks of exacerbation of the tuberculous process all through the period of pregnancy and a still greater risk in the few months after the confinement is over, if the tuberculosis be not adequately treated These risks can be greatly minimised by sanatorium régime, and this institutional care would appear to be the obvious course of action in all patients whose circumstances will permit of it The risks of second pregnancies must depend largely on the good sense of the parents and the wisdom of the physician in handling a difficult situation For the infant the prospect is not a hopeful one There is evidently a considerable risk of the infant dying of tuberculosis during the first year This risk can no doubt be mitigated, if not entirely eliminated, in better-class homes where good nursing and adequate precautions against infection can be adopted The treatment of tuberculosis is largely a financial question Amongst the hospital classes pregnancy supervening upon tuberculosis is a grave danger and the outlook is gloomy In the wealthier classes, where sanatorium treatment can be kept up for a long period and where the mother is not compelled to live in close contact with the infant from the moment of its birth, the outlook for both mother and child is obviously brighter

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CLXXXIV

THE TREATMENT OF INFECTION AT THE APICES OF TEETH

INFECTION at the apex of a tooth may be brought to notice in several ways, commonly as an acute alveolar abscess or as a chronic abscess discharging into the mouth by an obvious sinus It is not proposed here to discuss either of these conditions, but to confine attention to that form of apical infection which commonly occurs with no obvious signs or symptoms, and is only disclosed when a radiogram shows an area of rarefied bone immediately round the apex of a tooth or the apices of several teeth Such apical rarefaction ordinarily only occurs in "dead" teeth and nearly always in teeth the pulps of which have become exposed by the advance of dental caries and infected by organisms from the mouth and have died Those "dead" teeth in which the tooth pulp has been purposely devitalised by the dental surgeon should if his technique has been correct, be sterile at the apical portion of the pulp canal from the start, and so never show these rarefied areas, and in such teeth this is the rule

The importance of these otherwise signless and symptomless apical infections lies in the fact that they are usually found in the mouths of people who are seeking medical advice for general symptoms of a wide variety, for which no immediate cause can be found, and it is in the medical man's careful search for some source of focal infection that radiograms of the jaws frequently give the first intimation that such infections exist Moreover, these infections are more frequently found in people who take every care of their teeth, there is every reason why this should be so, because they occur far more commonly in filled dead teeth than in teeth with dead pulps which are left untreated, though they do occur in these latter also

Routine Treatment of an Infected "Dead" Tooth

A "dead" tooth with an infected pulp canal may or may not give an abnormal response to percussion (periodontitis) but the contents of the pulp chamber and canals will always be extremely foul Except at some three or four educational centres in various parts of the world where during the past few years other means have been tried, the ordinary routine treatment given by the dental surgeon preparatory to the insertion of a permanent filling in such a tooth is as follows —

The infected contents of the pulp canals are removed by mechanical means and the (attempted) sterilisation of these canals is carried out by means of sealing into the canals a dressing of a mixture of as powerful and penetrating antiseptics as one dare use consistent with non-injury to adjacent soft parts, particularly by leakage through the apical foramen of the tooth Usually such dressings are repeated several times, and occasionally many times

But the *only* signs that the tooth is ready to be filled—i e, that the root canal has been rendered sterile—which are available to the dental surgeon are these —

(1) The cessation of the clinical signs of periodontitis (which may never have been present at all)

(2) The sense of sight, that there are no obvious particles of matter left in the canals

3 The sense of smell, that the foulness has disappeared

These tests for sterility appear to me to be but feeble at the outset, particularly the third, our sense of smell is a poor sense, and with the powerful odours of the drugs which are used for antiseptic dressings about the sense of smell is of no value whatever, even to detect gross infection by gas-producing organisms—added to which is the fact, not sufficiently recognised by dental surgeons, that many infective organisms produce no smell at all on culture

After these precautions have been taken the root canals of these teeth are usually filled permanently with some such material as gutta-percha with or without the addition of antiseptic drugs, and the restoration of the tooth by one of the usual forms of filling is completed

Let it not be thought that the dental surgeon is careless in his treatment of such dead and infected teeth, because he certainly is not, the treatment and conservation of such teeth are invariably an anxiety to him Moreover, in the past the results of such treatment has been entirely justified, as many otherwise unsavable and offensive teeth have been rendered painless, comfortable, and fully functional for many years if not for the whole life of the individual However, it will be fairly obvious from the above remarks that the treatment of dead teeth is in an unsatisfactory state, and indeed this is so, for there is no proof that the root canal of the tooth, and still more the soft tissues beyond it, are really sterile Indeed, in my view, but few teeth which have become infected in the manner described are ever rendered sterile by the dental surgeon, but the inhibitory effect of the powerful drugs used on any micro-organisms present is such as usually to keep them in check Radiograms, however, too frequently show us that though teeth so treated may be entirely comfortable and function well, they have never really been sterilised, and that infection still persists and gives rise to the ordinary appearance of a rarefied periapical area

Can Infected Teeth be Sterilised?

In order to test out whether such infected teeth could be rendered sterile I induced several students interested in this matter to make some culture experiments and microscope slide films from such treated teeth *after they were thought to be clinically sterile.*

The drugs usually used for the dressing of such teeth are —

(1) A mixture of 40 per cent formalin 1 part, tricresol 1 part absolute alcohol 3 parts with the addition of a few minims of some essential oil to act as an analgesic

(2) Dichloramine T—used mainly in America

(3) Silver precipitated in situ from an antiseptic silver salt

(4) Many proprietary articles sold for this purpose, some of which are very efficient, and other mixtures

The antiseptic mixture (1) was used mostly and occasionally a proprietary article Precipitated silver was not used, because though I believe and am informed that the tooth itself really is sterilised when this is used, the soft tissues beyond are not, moreover, the tooth tissue is stained an unsightly colour, so the method is not available for anterior teeth

The routine for the experimental treatment of dead teeth with infected pulp canals was on the following lines —

First visit—Apply rubber dam. Empty pulp *chamber* thoroughly (not using any pressure towards apices) Fill chamber with a pledget of cotton-wool saturated with tricresol-formalin-alcohol solution, cover over with metal pulp cap *Seal* in with calxine Leave for 48 hours

Second visit—Apply rubber dam Remove contents of pulp canals thoroughly by mechanical means Wash out with 10 vol H_2O_2, follow with absolute alcohol Dry with hot air Fill root canals and pulp-chamber loosely with cotton-wool saturated with tricresol-formalin-alcohol solution Cover over and seal in as at first visit Leave for 48 hours

Third visit—Apply rubber dam and remove dressings If clinical appearances now indicate that tooth is ready to be filled permanently, wash out thoroughly with absolute alcohol, dry with hot air, place sterile paper point in root canal, cover and seal as before, leave for seven days (approximately)

Fourth visit—Apply rubber dam and remove dressings If clinical appearances still indicate that tooth is ready to be filled permanently, take two cultures for incubation and make two micro slide films (these last two operations under supervision) using the paper point removed from the root canal, and then redress as at second visit. If tooth is clinically not ready to fill, redress as at second visit and leave for 48 hours, and make cultures and films when apparently sterile, and so on, till the microscope tests are negative when the restoration may be completed.

The results of these experiments, as far as they went were not reassuring—indeed were very disappointing. Some 5 or 6 teeth were dressed and tested frequently over a period of six months and still were not sterile. A few others gave a similar result over rather longer periods, and one (fortunately owned by a bacteriologist) gave a sterile microscope test when weekly dressings had been continued for a year. Two others only gave positive sterile tests each after about six weeks' treatment. The tests were begun on some 30 teeth but patients (all but two being hospital patients) could not spare the time for the frequent and numerous visits needed and so only very few were really followed out. The matter is thus in urgent need of further research.

Conclusion

How, then, are we for the future to regard these dead teeth with infected pulp canals from the point of view of conservative dentistry? Let it be granted that when tested by cultures and films they can usually after prolonged treatment be rendered sterile. Then I think, we may say —

1. That for single-rooted teeth with straight pulp canals conservative treatment may be justified, but that the prolonged treatment, time occupied and necessary expense involved, will militate against such a course.
2. That for multi-rooted teeth (not so easy of access) or teeth with small and tortuous pulp canals extraction should be recommended.

Such is to my mind the only rational course—i e. teeth must either be proved sterile by culture or film, or extracted.

Many patients will object to such treatment as being too drastic, and many dental surgeons will object on account of the comfort and restoration of function which they can afford to such teeth in other ways. It must also be borne in mind that many people are walking about with many (up to eight or nine or more) such rarefactions at the apices of teeth in their mouths and no general or local symptoms whatever. On the other hand, the removal of one or two such infections in one mouth has in several cases known to me been followed almost immediately by the disappearance of the general symptoms complained of, for which no other cause could be found.

It would seem that until we have some more certain means of sterilising such teeth their conservation ought not lightly to be undertaken; till that time I would not take the responsibility of advising anyone to retain such infected areas in their mouths even if they were giving rise to no symptoms nor would I retain one myself. If conservative treatment is decided on the patient should be informed beforehand of the possible result.

INTERNATIONAL CONGRESS FOR LIFE-SAVING AND FIRST-AID.—The Third International Congress for Life-saving will be held at Amsterdam from Sept 6th to 11th under the presidency of Prince Henry of the Netherlands. Many different countries will be represented both officially and unofficially and national committees have been established all over the world in preparation for the Congress. Besides general sessions there will be meetings of the 11 sections, and more than 100 lectures have been arranged; there are also to be demonstrations of ambulance work and of saving the shipwrecked. The first international competition in first-aid will be a feature of the Congress, and visits will be paid to The Hague, Rotterdam and other interesting places; the municipalities of Amsterdam and Rotterdam are arranging to hold receptions. Members of the Congress will be able to get a Dutch visa for their passports without difficulty and accommodation in hotels or lodgings will be arranged as far as possible. The executive committee asks all those who wish to attend to send word without delay to the Secretary-General, Dr C J Mynlieff, Keizersgracht 131, Amsterdam.

Special Articles.

INCAPACITY FOR WORK

The New Memorandum of the Ministry of Health.

A FEW weeks ago[1] the Scottish Board of Health called the attention of insurance practitioners in Scotland to the sudden increase in the certification of claims for sickness and disablement benefit. The Minister of Health has now expressed his concern at the abnormal increase during the last two months in the number of insured persons in England and Wales receiving sickness and disablement benefit and the resulting heavy expenditure incurred by many approved societies. Information available from other sources does not indicate the prevalence of any marked epidemic or exceptional outbreak of sickness which would account for this increase in the number of cases of certified incapacity and it is significant that the ratio of expansion is not uniform throughout the country and that its geographical distribution corresponds closely with the incidence of unemployment due to the dispute in the coal trade. The memorandum upon the subject addressed to insurance practitioners runs as follows —

> The results of the examination of a large number of cases referred to referees, and in particular the high proportion of claimants who sign off in preference to presenting themselves for examination, suggest strongly that large numbers of insured persons have succeeded in obtaining or continuing to obtain medical certificates although they were not in fact incapable of work. The Minister cannot escape the conclusion that many practitioners in the industrial areas mainly affected have failed to appreciate the danger that in times of acute unemployment there is inevitably a tendency to magnify minor ailments and to claim sickness benefit in circumstances in which, under ordinary conditions no claim would be made. Normally the difference between sickness benefit and average earnings is sufficient to afford the employed person a substantial inducement not to leave work or to return to it as soon as he is able to do so; and doctors have, no doubt, in the past proceeded on the assumption that in cases in which there were no definite physical signs, the patient's account of his subjective symptoms might, in general, be accepted in the absence of any indication to the contrary. But in many areas this economic safeguard against ill-founded claims no longer exists, and the Minister fears that practitioners have not sufficiently realised that an increase in the number of claims in itself necessitates more than ordinary care in considering whether the statutory conditions for the receipt of sickness and disablement benefit have been fulfilled.
>
> He therefore desires to remind practitioners that the statutory test of title to these benefits is that the insured person has been rendered incapable of work by some specific disease or bodily or mental disablement and that strict regard must be had to this criterion in considering all cases coming before them. No practitioner is justified in allowing the economic position of the applicant for a certificate to lead him to adopt a less stringent standard than the Acts require; it should be remembered that any laxity in the issue of certificates, whether unconscious or deliberate, is extremely unfair to those doctors who have continued to take a strict view of their obligations under the Terms of Service. Moreover it must not be forgotten that excessive indulgence to individual members of approved societies must thereby deprive members in general of sums which might otherwise have been used in providing additional benefits in the future.

The Earlier Memorandum.

The opportunity has been taken to reissue simultaneously the memorandum prepared by the Ministry four years ago for the guidance of practitioners in interpreting the term "incapable of work." This memorandum made no claim to laying down legal definitions being content to summarise accepted views. The significant passages in it are the following:

> It has not been held to be necessary for the purpose of establishing a title to sickness or disablement benefit, that the insured person should be found to be incapable of work in the sense of being completely unable to carry out the

---

[1] THE LANCET July 10th p 97.

physical or mental processes which constitute "work." An insured person has been regarded as "incapable of work" when in such a condition, through some specific disease or bodily or mental disablement, that an attempt to work would be seriously prejudicial to his health

Secondly, though the fact that an insured person is unable to follow his ordinary occupation is not in itself sufficient to justify his being regarded as incapable of work, yet he would properly be so regarded if, as will ordinarily be the case, it appears probable that he will soon be able to resume his former work, and that it would therefore be unreasonable to expect him to undertake any other form of work in the meantime This is the criterion which doctors are ordinarily disposed to apply, and it suffices, no doubt, for the ordinary case of a short illness

There is, however, a group of cases which, though a minority, are yet considerable in number and of great importance in their potential effect on the sickness and disablement benefit funds, and in which other conditions need to be taken into account It is with regard to these that in the past there has been most misunderstanding by medical practitioners of the position as regards title to benefit At varying stages in the course of different diseases, or after the occurrence of particular injuries, it will become clear that there is no reasonable prospect of the patient again becoming able to resume his former occupation This may be apparent in some cases almost from the outset—for example, where a person whose work requires some particular manipulation has sustained an injury which immediately renders him permanently incapable of carrying out that manipulation, or where a person has become blind When this condition of permanent incapacity to resume the previous occupation has supervened, a different criterion from that of fitness for ordinary occupation must, it has been held, be applied, and the patient should not be certified as "incapable of work" unless in the doctor's opinion he is physically unable to perform any other suitable kind of remunerative work, whether at once or after a short course of training

A Difficult Situation

A close association has often been noted between sickness claims and social conditions, thus when wages fell and unemployment began to affect the mining industry from 1920 onwards, the incidence of reported accidents rose, while the occurrence of fatal accidents showed no such rise In a similar way the present industrial position is being associated with an abnormal increase in the number of persons receiving sickness and disablement benefit, an increase which the Ministry of Health point out in a recently published memorandum is not uniform throughout the country, but is distributed in close correspondence with the incidence of unemployment due to the dispute in the coal trade. It is an obvious presumption that the increase in applicants for certificates in respect of sickness and disablement benefit—in other words, of incapacity for work—represents a tendency to magnify minor ailments, so as to claim benefit, for which normally no claim would be made. Control of this tendency must always be difficult, especially as is pointed out in our correspondence columns when an insured person is free to change the doctor whose certification does not please him, but the Ministry rightly stress the point that the economic position of an applicant for a certificate under the Insurance Act should not affect the practitioner's judgment, and that the standard of disability—i e., of incapacity for work—should be maintained For this purpose the memorandum published some four years ago, and explaining the meaning of the term "incapable of work," is being simultaneously re-circulated to insurance practitioners It is useful that practitioners should be reminded in this way of their legal responsibilities when issuing certificates, but the medical profession can hardly resist the influence of removal of the great economic safeguard against poorly-founded claims, for it is a normal safeguard in this direction since by establishing a claim of disability the working income is reduced Moreover the absence of occupation in itself tends to introspection which may make manifest conditions, whether really latent or merely imaginary The cure for the abnormal rise in claims lies fundamentally not in an appeal to the medical profession to be exceptionally alive to malingering, but in resumption of the normal incentives to remunerative activity The new memorandum does not, we are sure, desire to reprove medicine for what medicine is in no way responsible, and if this impression were received publicly the position would be unfair to the profession Moreover the standard of ill-being in the nation, though improving, is low, it might more than occasionally justify certification for incapacity of persons who disregard their ills to the final detriment of their well-being.

REPORT OF THE LUNACY COMMISSION.

SOME CRITICAL VIEWS

THE Report of the Royal Commission on Lunacy and Mental Disorder, of which the main provisions were summarised in our last issue,[1] has, in many respects, received warm commendation from those interested in the prevention and early treatment of mental disorder It is generally agreed that the work of the Commission has been done in a thorough manner, that the Report is well-written, and that it contains a great deal of valuable information It seems probable, too, that a report so little controversial may lead to speedy legislation, which will be all to the good in so far as the long overdue permission is granted to local bodies to provide early treatment The view, however, is expressed that the public, and the medical public in particular, will need to scrutinise very closely the results of permissive legislation, a general and constant demand that the problem shall receive full and adequate handling must be maintained, in order to achieve results in the prevention of chronic mental disorder with its heavy burden to the community

Treatment without Certification

Some of those now engaged in the treatment of mental cases without certification may very naturally feel that the constructive proposals leave something to be desired No one will expect that, in the present time of economic stress, and under a Government pledged to economy, legislation of a very far-reaching nature involving much present expenditure and the initiation of a new service of preventive medicine is likely to be even proposed, much less passed by Parliament But a Royal Commission might surely put forward an ideal, and leave it for the practical politician to do the paring that may for the moment be necessary They do, indeed, point out that present expenditure on early cases may be productive of future saving—it may obviate the maintenance for life of cases coming under treatment too late for cure But the important part of their work—the consideration of provision for early treatment without certification—appears lacking in constructive ideals and imaginative foresight Very scant attention is paid to the actual provisions for care of the patient, the greater part of the report being concerned with (1) legal provisions long overdue, for treatment under a provisional order of those unable to cooperate and under a voluntary system for those who are able and willing to do so, and (2) the various local and central authorities responsible for such treatment The implication throughout is that the existing arrangements and institutions simply need extension, and it is not clearly and definitely stated how urgently separate and new institutions are necessary if the early treatment is to apply in fact to the mass of patients at present neglected. The Report suggests general hospitals, nursing homes, and mental hospitals and special clinics associated with any of these, but it merely advises that "it should be open to the local authority to provide such clinics" It does not put forward the difficulties and complications involved, nor even urge that any pressure should be brought to bear on the local authorities to make effective provision, without which little will materialise. General hospitals will not burden themselves with the procedure required by the Board of Control, nor gladly cooperate in the supervision which is necessary; nor again will they readily make suitable provision of specially trained nursing and medical staffs. It is well known that one mental patient of quite a mild type will arouse such fear and antagonism in a general hospital that the whole staff press for his immediate removal, while the neurotic is at present apt to be regarded there as a tiresome person having nothing the matter with him. Moreover, the accommodation at present in most general hospitals is unsuitable, and special buildings with gardens, open-air sleeping quarters, occupations and amusements and sound-proof, detached blocks for emergency treatment of transient noisy attacks, are essential for satisfactory early treatment. The out-patient clinic, however, may best be here.

---

[1] THE LANCET, July 31st, p 239

The provision of suitable admission blocks or villa colonies attached to, but well apart from the existing mental hospitals, may be the best solution for certain districts, but again the Commission has failed to emphasise that greatly increased medical and nursing staffs are absolutely essential for these. Further, it is only a limited proportion of the patients needing early treatment who will accept it when even the slightest association with the mental hospital is involved, and in practice it will be chiefly the cooperative section of the present mental hospital patients who apply for treatment there. Those neurotics who do not realise that their disorder is one of the mind will remain, as at present, untreated.

Special clinics can, and should, be provided; in London one exists already for such patients as have a claim on the London rates; when other local authorities are empowered, as the Commission suggests, to spend money for this purpose, it should not be impossible to arrange for a number of local bodies to cooperate in providing such accommodation as they need, or to take over existing convalescent and nursing homes and equip them suitably. It may be regretted that the Report has not put more forcibly the importance of devising such arrangements, since without them the result in practice may merely be a slight extension of treatment without certification in existing mental hospitals at the cheapest possible rate; this implies failure of a great opportunity for a far-sighted handling of the problem of relieving the community of its present burden of neurosis and psychosis.

Treatment with Certification.

From the point of view of those who have the care of private patients of the well-to-do classes, the recommendations concerning the unwilling patient are seen to have their drawbacks, especially when regarded from the point of view of the private patient. Two courses are to be made available, appearing to depend on the prognosis of the case. If the physician considers the case likely to recover within six months a provisional treatment order may be obtained. This is to necessitate a petition by a responsible relative, on which some disclosure of the patient's property is to be made. The petition is to be accompanied by one medical certificate of the usual kind, which must conclude by a statement that the condition of the patient is such that he should be detained under care and treatment. The petition and certificate are to be forwarded to a magistrate, specially appointed for the purpose, who is to see the patient, and if satisfied, give the provisional order. This order will only last for one month, at the end of which time the judicial authority must again visit the patient, and on a medical recommendation that the patient's illness is likely to terminate in the statutory time, may sign an extension of the provisional order for a further five months. At the end of this time the patient may have recovered or be sufficiently well to become a voluntary boarder. But if little or no progress towards recovery has taken place, then the usual reception order will be required, involving two medical certificates, and a further magisterial visit. In short, a year's illness may entail three medical certificates and three judicial examinations. This provisional treatment order is termed treatment without certification. Is it likely to be so regarded by the public? If it becomes law it may be found to be as objectionable to the private class of patient as the existing procedure. In fact, it is probable, writes one critic, that it will obtain, and deserve, the "stigma" that is so objectionable in the present form of certification. It is certain that many patients will be distressed by the double judicial examination in the first four weeks of illness.

It is true that the provisional order is to be used for those cases which are likely to recover in six months, the usual reception order being used for cases which are less favourable. But what physician will care to give a bad prognosis? In a mental case, what physician however experienced, can rightly give an unfavourable prognosis at the beginning of a mental illness? The obvious inference is that most cases will be admitted to care under a provisional order, and that the reception order, with two certificates, will have to be made at the end of six months in those cases which run an unfavourable course.

In view of the objection that many patients of the private class have to judicial visits, it is to be hoped that some modification of the suggested provisional order may be made.

JOURNÉES MÉDICALES DE PARIS

(BY OUR PARIS CORRESPONDENT.)

LARGE numbers of French and foreign doctors attended the Journees Medicales held at Paris from July 15th to 19th, when recognised authorities gave post-graduate lectures on medical and surgical methods or technique. The Congress was intended to refresh the knowledge of practitioners and to make them familiar with important modern advances, and it gave those present a chance of hearing some of the opinions now orthodox in France.

Amongst those who attended from abroad was Prof. E. A. Graham, of St. Louis, U.S.A., who gave an account of his work on the radiographic examination of the gall-bladder. He claims that cholecystography, the method which he devised in 1923, permits of early and accurate diagnosis of lesions of the gall-bladder which may otherwise present great difficulty.

An interesting demonstration was given by Dr. P. Ravaut, of the Hôpital St. Louis, who showed a series of 27 cases of lupus treated by diathermy coagulation. An early lesion, he said, can be effectively destroyed by this treatment at a single sitting, leaving the least possible scar, and it is thus a method of prophylaxis. Early diagnosis is very desirable, but even very extensive lupus can be dealt with if the treatment be repeated on several occasions.

Recto-sigmoidoscopy.

A session at the Grand Palais was devoted to the advantages of recto-sigmoidoscopy. This procedure, it was suggested, is far too seldom practised—partly because it is supposed to be difficult and partly because medical men are unaware of its many uses. Dr. Bensaude, of the Hôpital St. Antoine, laid stress on its value from two points of view, the diagnostic and the therapeutic. It ought, he said, to be the prevailing means of diagnosing cancer of the rectum, which is characterised on examination by its shape, its bright red colour, its friability, and its consistency, and by the obstruction which it causes to the passage of the rectoscope. Hæmorrhoids may either simulate or mask it. Sigmoidoscopy, said Dr. Bensaude, is necessary in cases of dysentery or dysenteric colitis, even if examination for parasites or bacteria prove positive, since cancer may complicate a case of dysentery or may occur in patients who are carriers of amœbæ. Some neoplasms look like benign polyps and their malignant nature can only be recognised at operation; villous tumours on the other hand, are frequently mistaken for cancer. Therapeutic endoscopy, he stated is used for three main purposes —in the treatment of piles, of polyps, and of rectal stricture In piles the use of sclerosing injections is giving remarkably satisfactory results and there are never any serious complications arising from them In all the benign new growths of the rectum electro-coagulation is the treatment of choice, and for rectal strictures the success of diathermy contrasts favourably with the failure of surgical intervention as hitherto practised

Peptone Therapy.

Dr Pasteur Vallery-Radot (Paris) gave a demonstration of the technique of skin reactions and the results to be got in cases of asthma, hay fever, urticaria, and other anaphylactic conditions A positive reaction, he said, should be regarded as an indication for specific treatment, but often, unfortunately, it is impossible to protect the patient from the protein which upsets him, and in these cases desensitisation is required In dealing with digestive anaphylaxis desensitisation may sometimes be brought about by giving increasing quantities of the harmful protein by the mouth over a period of several weeks, or the patient may be given, an hour after the food which affects him, an infinitesimal quantity of the very same food According to Dr Vallery-Radot, where the patient is troubled with respiratory anaphylaxis the desensitising protein should be given subcutaneously, or, better still, cutaneously This last method is without danger and simply consists in producing repeated skin reactions with the specific antigen over a period of several weeks It must be recognised, however, that though diagnostic skin reactions sometimes reveal the particular protein to blame for the patient's symptoms, nevertheless, more often than not, they are negative and throw no light on the culprit. In these circumstances non-specific desensitisation is needed In alimentary anaphylaxis a small dose of peptone—preferably polyvalent—should be given by mouth one hour after meals three times a day Eating between the three meals should be forbidden For asthma the peptone should be given by strictly intradermic injection, daily for about three weeks A 50 per cent solution of Witte's peptone may be used in doses of 0 1 to 0 3 c cm The treatment acts by producing a local reaction which determines a general shock; after a series of these shocks more or less permanent desensitisation may be hoped for.

Treatment and Prophylaxis of Diphtheria

The research done during the last few years on diphtheria—and especially the discoveries of Ramon of the Pasteur Institute—have improved the treatment and prophylaxis of diphtheria In a conference at the Hôpital des Enfants Malades, Dr Pierre Lereboullet said that early, intensive, and prolonged serotherapy should be the rule in treating diphtheritic sore-throat The doses, whilst varying with the duration and the gravity of the disease, ought to be much higher than is generally believed In an ordinary angina the least that should be injected is from 150 to 200 c cm, and the total dose, which ought never to be less than 500 c cm, could and should reach or even exceed 800 or 1000 c cm Thanks to these doses malignant diphtheria shows 80 per cent of cures Moreover, the massive and systematic use of serum hinders the appearance of paralysis For malignant diphtheria serotherapy should be associated with the administration of adrenalin subcutaneously and of suprarenal extract by the mouth Accidents with serum have been much diminished by the use of Ramon's purified serum, and diphtheria can also be prevented by lasting and harmless vaccination Two or three subcutaneous injections of Ramon's anatoxin are made at intervals of three weeks to bring about this protection, and the results are much more satisfactory than those of serum prophylaxis, whether in hospitals or communities or amongst families and contacts

Cancer of the Colon

The Société des Chirurgiens of Paris held on July 15th a special sitting in connexion with the Journées Medicales Among the more important communications was one by Dr Victor Pauchet who has come to the conclusion that operation is desirable in all cases where cancer of the intestine is so much as suspected Laparotomy is without risk, whereas delay may cost the patient his life The prognosis depends on the time of intervention as well as on the technique of the surgeon Diagnosis is difficult at first and Dr Pauchet advises exploratory laparotomy when any of the following symptoms are present—abdominal tumour, constipation with diarrhœa, pain accompanied by colic and rumbling, blood or mucus in the stools, obstruction or lacunæ seen with the X rays, or visible peristalsis He is not content with rectocolic endoscopy since it only shows tumours in the lower sigmoid

Lavage of the Vesiculæ Seminales

At the same session Dr Georges Luys demonstrated his technique for lavage of the seminal vesicles, which he has carried out more than 150 times The operation, he said, is very simple, although it may appear rather delicate The object is to get rid of those organisms which ordinary methods, such as massage of the vesiculæ or urethral dilatations, cannot touch An incision, 2 cm long, is made at the level of the root of the scrotum, the vas deferens is isolated carefully and 10 to 15 c cm of collargol are injected into its lumen with a trocar The patient is kept in bed on a sedative régime for four days The collargol remains in the vesiculæ seminales for some time—for at least four days and sometimes as long as three weeks The immediate and remote results of this method make it very satisfactory for the treatment of infected vesiculæ seminales

---

ROYAL MEDICAL BENEVOLENT FUND

At the last meeting of the Committee 35 cases were considered and £388 10*s* voted to 25 applicants The following is a summary of some of the cases relieved:—

Son, aged 15, of M D who died in 1922 Found living in undesirable surroundings A reputable firm gave him a job as telephone boy, but he was found quite incapable of doing the work The Fund has been asked to help with maintenance, as a home has been found for the lad where he will have every care and attention Arrangements have been made for private tuition, as his educational attainments are below those of a National schoolboy It is suggested that two years' rudimentary education should be given in his spare time It is hoped that other assistance will be forthcoming as the boy has the address and manners of a gentleman's son, though his education has been totally neglected Fund voted £26 in four quarterly instalments towards his maintenance

Widow, aged 60, of M R C S Eng who practised in London and died in 1908 Dependent on daughter, aged 36, who teaches French in Paris Mother and daughter live in one room at a cost of Fr 1115 and the latter receives Fr 700 a month She has been ill and the Fund has been approached to help in their distress Voted £12 in 12 monthly instalments of £1 each and a special grant of £5 Previous relief since 1913 amounted to £106

Widow, aged 71, of M R C S Eng who practised in London and died in 1913 Has a small cottage outside London and supplements her small income of £30 per annum by letting, from which she has received £41 during the last twelve months A friend has given £20 and she has been able to pay her way but asks for assistance for repairs as the rooms are in a bad condition for letting Voted £15 Previous relief since 1916 amounts to £28

Daughter, aged 76 of M R C S who was in the R.A M C and died in 1891 A condition of residence in a home is an income of £40 per annum and the applicant received only £32 per annum from the War Office Fund voted £20 in four quarterly instalments Previous relief since 1921 amounts to £70

Subscriptions may be sent to the Hon Treasurer, Sir Charters Symonds, at 11, Chandos-street, London, W 1

New Nurses' Home at West Derby —An extension of the nurses' home has been opened at the Alder Hey Hospital, Knotty Ash This hospital was built in 1914 and has nearly 1000 beds, chiefly used for the treatment of tuberculous and deformed children The nursing staff of 200 includes 100 pupils in training and the new extension, which almost doubles the accommodation, has cost about £17,000

Correspondence.

"Audi alteram partem."

THE EX-BABY.

To the Editor of THE LANCET.

SIR,—I was much interested in reading your annotation in THE LANCET of July 24th, and at once referred to the report of the Westminster Maternity and Child Welfare Conference in your issue of July 17th. My special interest refers to the gap in medical supervision between infancy and school entrance pointed out by Dame Janet Campbell. This gap I have myself drawn attention to more than once in connexion especially with squint. The subject of squint seems to have been mentioned but not enlarged upon at the Welfare Conference. Yet squint and its underlying principal ætiological factor, the refraction error, are together of such importance to the visual efficiency of the nation that I would ask you, Sir, by way of emphasising the importance of the "ex-baby," to allow me to quote from two recent communications of my own. At the Ophthalmological Congress at Oxford in 1924, in my opening paper upon the treatment of squint,[1] I said:—

> "May I put theory on one side and say that taking juvenile squints all over, everyone will agree that the earlier we can establish a meticulous optical correction after the appearance of the squint the greater will be the number of cases which improve in visual acuity and ultimately recover? Nevertheless, our object and ideal should be the correction of the refraction error before the squint occurs. This ideal seems at the present moment impossible to reach on account of the obvious difficulty of examining children of pre-school age."

Again, at the 1926 Congress of the Ophthalmological Society, U.K., when dealing with Birth Injuries of the Eye, the following will be found (when the Transactions for 1926 are published) in my opening paper:—

> "At this point I would like to express my conviction of the value which could be obtained from a link record of each individual from birth to school age. School medical statistics are capable of providing a record back to 5 or 6 years of age of any child. If only we could have the medical history from birth to school age I feel convinced we should be able to obtain light on a variety of subjects."

A letter to the Editor is not the place in which to enlarge upon a subject of this kind, yet my very considerable experience of children's eye diseases as ophthalmic surgeon to a large education authority impels me to encroach upon your space in order to support Dame Janet Campbell's plea for the filling of the gap in general medical control of the child to which she has referred.—I am, Sir, yours faithfully,

Stirling, July 27th, 1926. ERNEST THOMSON.

To the Editor of THE LANCET.

SIR,—The gap in our organisation for the care of the child of pre-school age, to which attention has been drawn by Dame Janet Campbell, and on which you comment in your issue of July 24th, does not exist everywhere, and would not have existed anywhere if, in 1918 the Government had made the Maternity and Child Welfare Act compulsory in place of optional, and if the powers which this Act gives were faithfully carried out by local authorities. In many of the areas where the Act has been adopted—and certainly in this city—there is no gap. Children are supervised by the maternity and child welfare officials from their antenatal period to the end of the fourth year, and while it cannot be contended that the supervision is anything like complete, it may justly be claimed that there is no gap. The first centre day in every month at each of the 11 centres in Newcastle is devoted exclusively to children aged from 1½ to 5 years, and in 1925 2000 of these children attended our centres 16,000 times.—I am, Sir, yours faithfully,

A. F. G. SPINKS,
Maternity and Child Welfare Medical Officer, Newcastle upon Tyne.

July 29th, 1926.

CERTIFICATION OF INCAPACITY FOR WORK

To the Editor of THE LANCET.

SIR,—A memorandum has just been issued to insurance practitioners by the Minister of Health on the above subject. It is a surprise to me that it has not been forthcoming at an earlier date. Under the present regulations an insured person is free to change his doctor whenever he likes, the obvious result being that if his doctor will not certify him unfit he at once changes to one who will. As long as the panel doctor is subject to a threat of changing doctors if he does not carry out his patient's wishes the increase in certification is bound to take place. It is obvious to any right-thinking person that a constant change of doctor at will in a Government medical service (and the panel service is obviously one) is subversive to any form of discipline. It is a mystery to me why the British Medical Association was so keen on it. Why not suggest it also for Navy, Army and Air Force? The result is that in order to be a successful panel doctor the most important thing is to offer a certificate of incapacity to all who ask for it, whether they are sick or not; a knowledge of one's job is a secondary consideration. I know from personal experience that if one tries to do one's job conscientiously it is disastrous to one's pocket, and I strongly advise young men entering practice to avoid the panel as the devil would holy water. The panel service ought to be made a whole-time one at fixed salaries and pensions and discipline for patients, or else scrapped; at present it is a heartbreaking and degrading service for a doctor who wants to do his job conscientiously.

I am, Sir, yours faithfully,

Exeter, July 24th, 1926. CHARLES H. CARROLL.

THE DEFINITION OF DRUNKENNESS

To the Editor of THE LANCET.

SIR,—An account has appeared in local newspapers of the trial and acquittal of a motorist alleged to be drunk, which occurred here recently.

As I am told that this is the first case of the kind to be tried at Quarter Sessions it may well be of national importance. According to the police evidence the accused could not stand or walk alone on admission to the police station. He called his own doctor who examined him, but who was not called by the defence. Presumably, therefore, this doctor's evidence would not have been in favour of the prisoner. I saw the man shortly after the other doctor—that is, more than one hour after his admission to the cells. He was then familiar, jocular, flushed, and acted foolishly, as described in the paper, but he could walk all right and all his movements were fairly well coördinated. He came before the magistrates but elected to be tried at Quarter Sessions. At the latter court I gave evidence, and when asked if he were drunk when I saw him I said "Yes." Other witnesses, however, did not use this term, but simply said that he was, in their opinion, "under the influence of drink."

As this case may create a precedent it is very important to have an authoritative definition of the term "drunk." The jury apparently did not consider that a man who was "under the influence of drink" and whose judgment and discretion were obviously gone, was necessarily "drunk."

The man who is "drunk and incapable" is no danger to the public as he cannot drive a car. The man who is a real danger is one who is less inebriated but who is self-confident and reckless, but who, if the above precedent be followed, will never be convicted.

The result of this trial will be to discourage the police from taking any action in such cases until some accident has occurred. In the Mental Deficiency Act, which deals with somewhat similar points as regards responsibility, definitions of what is meant by the terms 'imbecile," "a feeble-minded person" &c., are given, and it is surely possible and quite

THE EX-BABY.

To the Editor of THE LANCET

SIR,—I was much interested in reading your annotation in THE LANCET of July 24th, and at once referred to the report of the Westminster Maternity and Child Welfare Conference in your issue of July 17th My special interest refers to the gap in medical supervision between infancy and school entrance pointed out by Dame Janet Campbell This gap I have myself drawn attention to more than once in connexion especially with squint The subject of squint seems to have been mentioned but not enlarged upon at the Welfare Conference Yet squint and its underlying principal ætiological factor, the refraction error, are together of such importance to the visual efficiency of the nation that I would ask you, Sir, by way of emphasising the importance of the "ex-baby," to allow me to quote from two recent communications of my own At the Ophthalmological Congress at Oxford in 1924, in my opening paper upon the treatment of squint,[1] I said —

> "May I put theory on one side and say that taking juvenile squints all over, everyone will agree that the earlier we can establish a meticulous optical correction after the appearance of the squint the greater will be the number of cases which improve in visual acuity and ultimately recover ? Nevertheless, our object and ideal should be the correction of the refraction error before the squint occurs This ideal seems at the present moment impossible to reach on account of the obvious difficulty of examining children of pre-school age."

Again, at the 1926 Congress of the Ophthalmological Society, U K , when dealing with Birth Injuries of the Eye, the following will be found (when the Transactions for 1926 are published) in my opening paper —

> "At this point I would like to express my conviction of the value which could be obtained from a link record of each individual from birth to school age School medical statistics are capable of providing a record back to 5 or 6 years of age of any child. If only we could have the medical history from birth to school age I feel convinced we should be able to obtain light on a variety of subjects "

A letter to the Editor is not the place in which to enlarge upon a subject of this kind, yet my very considerable experience of children's eye diseases as ophthalmic surgeon to a large education authority impels me to encroach upon your space in order to support Dame Janet Campbell's plea for the filling of the gap in general medical control of the child to which she has referred —I am, Sir, yours faithfully,

Stirling, July 27th, 1926 ERNEST THOMSON

To the Editor of THE LANCET

SIR,—The gap in our organisation for the care of the child of pre-school age, to which attention has been drawn by Dame Janet Campbell, and on which you comment in your issue of July 24th, does not exist everywhere, and would not have existed anywhere if, in 1918 the Government had made the Maternity and Child Welfare Act compulsory in place of optional, and if the powers which this Act gives were faithfully carried out by local authorities In many of the areas where the Act has been adopted—and certainly in this city—there is no gap Children are supervised by the maternity and child welfare officials from their antenatal period to the end of the fourth year, and while it cannot be contended that the supervision is anything like complete, it may justly be claimed that there is no gap The first centre day in every month at each of the 11 centres in Newcastle is devoted exclusively to children aged from 1½ to 5 years, and in 1925 2000 of these children attended our centres 16,000 times —I am, Sir, yours faithfully,

A. F G. SPINKS,
Maternity and Child Welfare Medical
Officer, Newcastle upon-Tyne

CERTIFICATION OF INCAPACITY FOR WORK

To the Editor of THE LANCET

SIR,—A memorandum has just been issued to insurance practitioners by the Minister of Health on the above subject It is a surprise to me that it has not been forthcoming at an earlier date Under the present regulations an insured person is free to change his doctor whenever he likes, the obvious result being that if his doctor will not certify him unfit he at once changes to one who will As long as the panel doctor is subject to a threat of changing doctors if he does not carry out his patient's wishes, the increase in certification is bound to take place It is obvious to any right-thinking person that a constant change of doctor at will in a Government medical service (and the panel service is obviously one) is subversive to any form of discipline It is a mystery to me why the British Medical Association was so keen on it Why not suggest it also for Navy, Army, and Air Force ? The result is that in order to be a successful panel doctor the most important thing is to offer a certificate of incapacity to all who ask for it, whether they are sick or not , a knowledge of one's job is a secondary consideration I know from personal experience that if one tries to do one's job conscientiously it is disastrous to one's pocket, and I strongly advise young men entering practice to avoid the panel as the devil would holy water The panel service ought to be made a whole-time one at fixed salaries and pensions and discipline for patients, or else scrapped ; at present it is a heartbreaking and degrading service for a doctor who wants to do his job conscientiously

I am, Sir, yours faithfully,

Exeter, July 24th, 1926 CHARLES H CARROLL.

THE DEFINITION OF DRUNKENNESS.

To the Editor of THE LANCET

SIR,—An account has appeared in local newspapers of the trial and acquittal of a motorist alleged to be drunk, which occurred here recently

As I am told that this is the first case of the kind to be tried at Quarter Sessions it may well be of national importance According to the police evidence the accused could not stand or walk alone on admission to the police station He called his own doctor, who examined him, but who was not called by the defence Presumably, therefore, this doctor's evidence would not have been in favour of the prisoner I saw the man shortly after the other doctor—that is, more than one hour after his admission to the cells He was then familiar, jocular, flushed, and acted foolishly, as described in the paper ; but he could walk all right and all his movements were fairly well coordinated He came before the magistrates, but elected to be tried at Quarter Sessions At the latter court I gave evidence, and when asked if he were drunk when I saw him, I said "Yes." Other witnesses, however, did not use this term, but simply said that he was, in their opinion, "under the influence of drink "

As this case may create a precedent it is very important to have an authoritative definition of the term "drunk." The jury apparently did not consider that a man who was "under the influence of drink," and whose judgment and discretion were obviously gone, was necessarily "drunk."

The man who is "drunk and incapable" is no danger to the public as he cannot drive a car The man who is a real danger is one who is less inebriated, but who is self-confident and reckless, but who, if the above precedent be followed, will never be convicted

The result of this trial will be to discourage the police from taking any action in such cases until some accident has occurred In the Mental Deficiency Act, which deals with somewhat similar points as regards responsibility, definitions of what is meant by the terms "imbecile" "a feeble-minded person" &c , are given, and it is surely possible and quite endoscopy, he stated is used for three main purposes—in the treatment of piles of polyps, and of rectal stricture In piles the use of sclerosing injections is giving remarkably satisfactory results and there are never any serious complications arising from them In all the benign new growths of the rectum electrocoagulation is the treatment of choice, and for rectal strictures the success of diathermy contrasts favourably with the failure of surgical intervention as hitherto practised

Peptone Therapy

Dr Pasteur Vallery-Radot (Paris) gave a demonstration of the technique of skin reactions and the results to be got in cases of asthma, hay fever, urticaria, and other anaphylactic conditions A positive reaction, he said, should be regarded as an indication for specific treatment, but often, unfortunately, it is impossible to protect the patient from the protein which upsets him, and in these cases desensitisation is required In dealing with digestive anaphylaxis desensitisation may sometimes be brought about by giving increasing quantities of the harmful protein by the mouth over a period of several weeks, or the patient may be given, an hour after the food which affects him, an infinitesimal quantity of the very same food According to Dr Vallery-Radot, where the patient is troubled with respiratory anaphylaxis the desensitising protein should be given subcutaneously, or, better still, cutaneously This last method is without danger and simply consists in producing repeated skin reactions with the specific antigen over a period of several weeks It must be recognised, however, that though diagnostic skin reactions sometimes reveal the particular protein to blame for the patient's symptoms, nevertheless, more often than not, they are negative and throw no light on the culprit In these circumstances non-specific desensitisation is needed In alimentary anaphylaxis a small dose of peptone—preferably polyvalent—should be given by mouth one hour after meals three times a day Eating between the three meals should be forbidden For asthma the peptone should be given by strictly intradermic injection, daily for about three weeks A 50 per cent solution of Witte's peptone may be used in doses of 0 1 to 0 3 c cm The treatment acts by producing a local reaction which determines a general shock, after a series of these shocks more or less permanent desensitisation may be hoped for

Treatment and Prophylaxis of Diphtheria

The research done during the last few years on diphtheria—and especially the discoveries of Ramon of the Pasteur Institute—have improved the treatment and prophylaxis of diphtheria In a conference at the Hôpital des Enfants Malades, Dr Pierre Lereboullet said that early, intensive, and prolonged serotherapy should be the rule in treating diphtheritic sore-throat The doses, whilst varying with the duration and the gravity of the disease, ought to be much higher than is generally believed In an ordinary angina the least that should be injected is from 150 to 200 c cm, and the total dose, which ought never to be less than 500 c cm, could and should reach or even exceed 800 or 1000 c cm Thanks to these doses malignant diphtheria shows 80 per cent of cures Moreover, the massive and systematic use of serum hinders the appearance of paralysis For malignant diphtheria serotherapy should be associated with the administration of adrenalin subcutaneously and of suprarenal extract by the mouth Accidents with serum have been much diminished by the use of Ramon's purified serum, and diphtheria can also be prevented by lasting and harmless vaccination Two or three subcutaneous injections of Ramon's anatoxin are made at intervals of three weeks to bring about this protection, and the results are much more satisfactory than those of serum prophylaxis, whether in families and hospitals or communities or amongst contacts

Cancer of the Colon

The Société des Chirurgiens of Paris held on July 15th a special sitting in connexion with the Journees Médicales Among the more important communications was one by Dr Victor Pauchet who has come to the conclusion that operation is desirable in all cases where cancer of the intestine is so much as suspected Laparotomy is without risk, whereas delay may cost the patient his life The prognosis depends on the time of intervention as well as on the technique of the surgeon Diagnosis is difficult at first and Dr Pauchet advises exploratory laparotomy when any of the following symptoms are present—abdominal tumour, constipation with diarrhœa, pain accompanied by colic and rumbling, blood or mucus in the stools, obstruction or lacunæ seen with the X rays, or visible peristalsis He is not content with rectocolic endoscopy since it only shows tumours in the lower sigmoid

Lavage of the Vesiculæ Seminales

At the same session Dr Georges Luys demonstrated his technique for lavage of the seminal vesicles, which he has carried out more than 150 times The operation, he said, is very simple, although it may appear rather delicate The object is to get rid of those organisms which ordinary methods, such as massage of the vesiculæ or urethral dilatations, cannot touch An incision, 2 cm long, is made at the level of the root of the scrotum; the vas deferens is isolated carefully and 10 to 15 c cm of collargol are injected into its lumen with a trocar. The patient is kept in bed on a sedative régime for four days The collargol remains in the vesiculæ seminales for some time—for at least four days and sometimes as long as three weeks The immediate and remote results of this method make it very satisfactory for the treatment of infected vesiculæ seminales

ROYAL MEDICAL BENEVOLENT FUND

AT the last meeting of the Committee 35 cases were considered and £388 10s voted to 25 applicants The following is a summary of some of the cases relieved —

Son, aged 15, of M D who died in 1922 Found living in undesirable surroundings A reputable firm gave him a job as telephone boy, but he was found quite incapable of doing the work The Fund has been asked to help with maintenance, as a home has been found for the lad where he will have every care and attention Arrangements have been made for private tuition, as his educational attainments are below those of a National schoolboy It is suggested that two years' rudimentary education should be given in his spare time It is hoped that other assistance will be forthcoming as the boy has the address and manners of a gentleman's son, though his education has been totally neglected Fund voted £26 in four quarterly instalments towards his maintenance

Widow, aged 60, of M R C S Eng who practised in London and died in 1908 Dependent on daughter, aged 36, who teaches French in Paris Mother and daughter live in one room at a cost of Fr 1115 and the latter receives Fr 700 a month She has been ill and the Fund has been approached to help in their distress Voted £12 in 12 monthly instalments of £1 each, and a special grant of £5 Previous relief since 1913 amounted to £106

Widow, aged 71, of M R C S Eng who practised in London and died in 1913 Has a small cottage outside London and supplements her small income of £30 per annum by letting, from which she has received £41 during the last twelve months A friend has given £20 and she has been able to pay her way, but asks for assistance for repairs as the rooms are in a bad condition for letting Voted £15 Previous relief since 1916 amounts to £28

Daughter, aged 76 of M R C S who was in the R A M C and died in 1891 A condition of residence in a home is an income of £40 per annum and the applicant received only £32 per annum from the War Office Fund voted £20 in four quarterly instalments Previous relief since 1921 amounts to £70

Subscriptions may be sent to the Hon Treasurer, Sir Charters Symonds, at 11, Chandos street, London, W 1

NEW NURSES' HOME AT WEST DERBY —An extension of the nurses' home has been opened at the Alder Hey Hospital, Knotty Ash This hospital was built in 1914 and has nearly 1000 beds, chiefly used for the treatment of tuberculous and deformed children The nursing staff of 200 includes 160 pupils in training, and the new extension, which almost doubles the accommodation, has cost about £17,000

THE EX-BABY.

To the Editor of THE LANCET

SIR,—I was much interested in reading your annotation in THE LANCET of July 24th, and at once referred to the report of the Westminster Maternity and Child Welfare Conference in your issue of July 17th. My special interest refers to the gap in medical supervision between infancy and school entrance pointed out by Dame Janet Campbell. This gap I have myself drawn attention to more than once in connexion especially with squint. The subject of squint seems to have been mentioned but not enlarged upon at the Welfare Conference. Yet squint and its underlying principal ætiological factor, the refraction error, are together of such importance to the visual efficiency of the nation that I would ask you, Sir, by way of emphasising the importance of the "ex-baby," to allow me to quote from two recent communications of my own. At the Ophthalmological Congress at Oxford in 1924, in my opening paper upon the treatment of squint,[1] I said:—

> "May I put theory on one side and say that taking juvenile squints all over everyone will agree that the earlier we can establish a meticulous optical correction after the appearance of the squint the greater will be the number of cases which improve in visual acuity and ultimately recover? Nevertheless, our object and ideal should be the correction of the refraction error before the squint occurs. This ideal seems at the present moment impossible to reach on account of the obvious difficulty of examining children of pre-school age."

Again, at the 1926 Congress of the Ophthalmological Society, U.K., when dealing with Birth Injuries of the Eye, the following will be found (when the Transactions for 1926 are published) in my opening paper:—

> "At this point I would like to express my conviction of the value which could be obtained from a link record of each individual from birth to school age. School medical statistics are capable of providing a record back to 5 or 6 years of age of any child. If only we could have the medical history from birth to school age I feel convinced we should be able to obtain light on a variety of subjects."

A letter to the Editor is not the place in which to enlarge upon a subject of this kind, yet my very considerable experience of children's eye diseases as ophthalmic surgeon to a large education authority impels me to encroach upon your space in order to support Dame Janet Campbell's plea for the filling of the gap in general medical control of the child to which she has referred.—I am, Sir, yours faithfully,

Stirling, July 27th, 1926. ERNEST THOMSON.

To the Editor of THE LANCET

SIR,—The gap in our organisation for the care of the child of pre-school age, to which attention has been drawn by Dame Janet Campbell, and on which you comment in your issue of July 24th, does not exist everywhere, and would not have existed anywhere if, in 1918, the Government had made the Maternity and Child Welfare Act compulsory in place of optional, and if the powers which this Act gives were faithfully carried out by local authorities. In many of the areas where the Act has been adopted—and certainly in this city—there is no gap. Children are supervised by the maternity and child welfare officials from their antenatal period to the end of the fourth year, and while it cannot be contended that the supervision is anything like complete, it may justly be claimed that there is no gap. The first centre day in every month at each of the 11 centres in Newcastle is devoted exclusively to children aged from 1½ to 5 years, and in 1925 2000 of these children attended our centres 16,000 times.—I am, Sir, yours faithfully,

A. F. G. SPINKS,
Maternity and Child Welfare Medical
July 29th, 1926. Officer, Newcastle upon Tyne.

CERTIFICATION OF INCAPACITY FOR WORK.

To the Editor of THE LANCET.

SIR,—A memorandum has just been issued to insurance practitioners by the Minister of Health on the above subject. It is a surprise to me that it has not been forthcoming at an earlier date. Under the present regulations an insured person is free to change his doctor whenever he likes, the obvious result being that if his doctor will not certify him unfit he at once changes to one who will. As long as the panel doctor is subject to a threat of changing doctors if he does not carry out his patient's wishes the increase in certification is bound to take place. It is obvious to any right-thinking person that a constant change of doctor at will in a Government medical service (and the panel service is obviously one) is subversive to any form of discipline. It is a mystery to me why the British Medical Association was so keen on it. Why not suggest it also for Navy, Army, and Air Force? The result is that in order to be a successful panel doctor the most important thing is to offer a certificate of incapacity to all who ask for it, whether they are sick or not; a knowledge of one's job is a secondary consideration. I know from personal experience that if one tries to do one's job conscientiously it is disastrous to one's pocket, and I strongly advise young men entering practice to avoid the panel as the devil would holy water. The panel service ought to be made a whole-time one at fixed salaries and pensions and discipline for patients, or else scrapped: at present it is a heartbreaking and degrading service for a doctor who wants to do his job conscientiously.

I am, Sir, yours faithfully,

Exeter, July 24th, 1926. CHARLES H. CARROLL.

THE DEFINITION OF DRUNKENNESS

To the Editor of THE LANCET

SIR,—An account has appeared in local newspapers of the trial and acquittal of a motorist alleged to be drunk, which occurred here recently.

As I am told that this is the first case of the kind to be tried at Quarter Sessions it may well be of national importance. According to the police evidence the accused could not stand or walk alone on admission to the police station. He called his own doctor who examined him, but who was not called by the defence. Presumably, therefore, this doctor's evidence would not have been in favour of the prisoner. I saw the man shortly after the other doctor—that is, more than one hour after his admission to the cells. He was then familiar, jocular, flushed, and acted foolishly as described in the paper, but he could walk all right and all his movements were fairly well coordinated. He came before the magistrates, but elected to be tried at Quarter Sessions. At the latter court I gave evidence, and when asked if he were drunk when I saw him, I said "Yes." Other witnesses, however, did not use this term, but simply said that he was, in their opinion, "under the influence of drink."

As this case may create a precedent it is very important to have an authoritative definition of the term "drunk." The jury apparently did not consider that a man who was "under the influence of drink" and whose judgment and discretion were obviously gone was necessarily "drunk."

The man who is "drunk and incapable" is no danger to the public as he cannot drive a car. The man who is a real danger is one who is less inebriated, but who is self-confident and reckless, but who, if the above precedent be followed, will never be convicted.

The result of this trial will be to discourage the police from taking any action in such cases until some accident has occurred. In the Mental Deficiency Act, which deals with somewhat similar points as regards responsibility, definitions of what is meant by the terms "imbecile," "a feeble-minded person," &c., are given, and it is surely possible and quite as important to define what is meant by the term "drunk" *as used in this recent Act* This appears to be a point which might well be raised by the medical members in Parliament, or taken up more vigorously and without delay by the B M A

Obituary.

JOHN CHRISTIE McVAIL, M D, C M ST AND AND GLASG, LL D, F R F P S G, D P H CAMB,

DEPUTY CHAIRMAN, NATIONAL INSURANCE, SCOTLAND

WE regret to announce the death of John Christie McVail, who died on Thursday, July 29th, at the age of 77

Born at Kilmarnock, he was the son of the late James McVail of that city, and was educated at the Universities of St Andrews and Glasgow He graduated in medicine at the former University in 1873, proceeding to the doctorate two years later, and was one of the first to take the newly-instituted Diploma of Public Health at the University of Cambridge He practised in Kilmarnock for nearly 20 years, until he was appointed medical officer of health in 1891 for the combined counties of Stirling and Dumbarton, and we owe to Sir Leslie MacKenzie the following appreciation of McVail alike as a practitioner and as an official

"My first meeting with Dr John C McVail was in 1891 He had been appointed medical officer of health for the combined counties of Stirling and Dumbarton He was just winding-up his practice in Kilmarnock I spent two days with him, and I began to understand the strength of intellect and will that enabled him to conduct a heavy private practice and yet to find time and energy for the general studies embodied in 'Vaccination Vindicated' and many other productions of those 18 years A man of McVail's ambitions and brains would find new problems in any profession, but his interest in vaccination was a reaction to a great epidemic of small-pox He could not be satisfied until he had gone into the whole problem It is only a few years ago that, in a course of public lectures, he gave his estimate of the later developments He was also in those days keenly interested in antiseptic surgery He was a student when Lister taught, but he retained to the end a certain critical attitude about the data on which the Listerian propositions and practices were founded He used to joke about the 'statistical conscience' and the way it operated in suppressing or 'explaining' unfavourable cases But even in his practice in Kilmarnock the public health interest became manifest, and we may say that McVail passed into the health service because he had seen how much could be done if the organisation for prevention were once properly developed Meanwhile his work on small-pox made him one with the chief medical officers of the English Local Government Board—Buchanan, Power, and others When the Vaccination Commission was formed, McVail was, of course, a leading witness and adviser

"The counties of Stirling and Dumbarton gave scope for his superabundant energies For McVail was a big, strong man mentally as well as physically He was by nature a man of power He 'carried weight' and, in the 'nineties of last century, when county health organisation was a blank, McVail was just the kind of personality to do in his counties what men like Gairdner and Burn Russell (two much-admired seniors) had done in the city of Glasgow He himself was senior to most of us He rejoiced in argument He could give and take hard hits, but always and everywhere he impressed men with his earnestness And there was always at the end even of the warmest encounters the gracious laugh of the serious man whose imagination was on fire with great social movements

"When the great Poor-law Commission was instituted, Dr McVail was appointed a special commissioner to investigate certain phases of English Poor-law The report he produced is among the best of the documents published by that Commission It still repays study, for it contained many carefully-worded descriptions of actual conditions It was not a sheaf of statistics, it was a thing of flesh and blood Documents like these become permanent 'sources' for the research of the next generation His main recommendation (the extension of the provident dispensary conception) did not impress me, but it reflected McVail's strongly 'voluntaristic' attitude

"He had an immense belief in 'voluntaristic' methods of medical administration, and it was his strong bias in this respect that made him enthusiastic over the National Health Insurance Act of 1911 When that Act was passed, he was already 62—that is, within three years of the normal civil service superannuation age, but so keen was he to see the working of the great experiment from within that he asked and obtained the office of Medical Commissioner of the Scottish Insurance Commission I wrote of him then that, though he was 62 years old he had the working brain of 42

"I could give many details of that landslide in the medical world All I need say is that McVail at 62 had his greatest fight before him At first he was acutely disappointed at the medical reception of the Act, but, as years went on, he grew more at ease in his feelings, and from his double experience first in practice, then in administration, he probably helped to prepare the way for the larger developments now emerging in health administration He certainly did a great deal to emphasise the preventive aspects of medicine This was the note of all his public utterances for his ten years of Government service

"Incidentally, when the Scottish Board of Health was formed, McVail became a member of it by transference, and thus a friendly cooperation begun when we were medical officers of health continued between colleagues in the same department of the civil service

"Like all distinguished medical officers of health, McVail had his full share of Parliamentary and Commission work He was a strenuous advocate, and never failed to impress committees and commissions as a man of grasp and sincerity It would take me too long to tell of his work in housing, lecturing, and propaganda It is enough to say that he never became indifferent to new movements He kept touch with the younger generation of medical men

"It was in October, 1925, that I met him for the last time at the annual meeting of the London School of Hygiene It was his seventy-fifth birthday He looked as bright and keen as that evening when I was his guest at THE LANCET centenary dinner But, knowing the truth, I could see in his face little lines that told me their story But he kept in the fighting line as long as physical strength permitted him As late as November last year he took the chair at a meeting of the Epidemiological, and sent me a message to come His mind remained young and active to the end It was a profound gratification to talk with him We always wandered into the larger questions of politics and social evolution, sometimes exchanging much argument on the more subtle questions of philosophy He belonged to a generation of men that included Gairdner, the two Cairds, Kelvin, Lister, Burn Russell, and to all of these, as to McVail, it was part of their religion to look at life as a whole and not to let any section of it draw the mind into mere specialism or the character into mere fanaticism McVail was a big man, and I am glad to have known him for five-and-thirty years"

In 1908 McVail became a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow and from the University he later received the hon degree of LL D, and his numerous appointments speak of the public esteem in which he was held He was at the time of his death President of the Epidemiological Section of the Royal Society of Medicine. he was an ex-president of the Society of Medical Officers of Health, and was for ten years Crown Member for Scotland upon the General Medical Council, succeeding his brother Sir David McVail In 1906 he was Lane lecturer of the Cooper Medical College San Francisco a foundation which has always attracted from England the famous exponents of our science in every direction In 1919 he delivered the Milroy lectures for the Royal College of Physicians of London taking as his subject "Half a Century of Small-pox and Vaccination"

He was a prominent member of the British Medical Association where he held many offices, and from the Royal Society he received the Jenner Medal In Scotland he acted as an examiner of medical jurisprudence and also in public health at all the four Universities of St Andrews, Edinburgh Glasgow. and Aberdeen, while he was also on the examining body of the Scottish Conjoint Board.

McVail was a clear and fearless writer as he showed nearly 40 years ago in "Vaccination Vindicated" to which reference has already been made He returned to this subject treating vaccination as a branch of preventive medicine in a contribution to Allbutt and Rolleston's "System of Medicine' and a little later wrote for the Transactions of the Epidemiological Society a summary of the work of the Royal Commission on Vaccination with a review of the statement of dissentient statements The results of his work as medical investigator to the Royal Commission on Poor-law made up a large section of that report, while to the Transactions of the Sanitary Institute and in the *British Medical Journal* and THE LANCET he made many important contributions Much of the work which he did for THE LANCET was editorial in nature, and throughout many years we found in McVail a wise counsellor on all questions of public health, especially where public rights and professional privileges appeared to make imperfect contact

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 24TH, 1926

Notifications—The following cases of infectious disease were notified during the week—Small-pox 91 (last week 157), scarlet fever, 1274, diphtheria, 895, enteric fever, 86, pneumonia 436 puerperal fever, 44 cerebro-spinal fever, 7, acute poliomyelitis, 16. acute polio-encephalitis, 3, encephalitis lethargica, 39, dysentery, 6, ophthalmia neonatorum, 113 There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths—In the aggregate of great towns, including London there were no deaths from small-pox, none from enteric fever, 14 (3) from measles 3 (0) from scarlet fever, 31 (3) from whooping-cough, 25 (10) from diphtheria, 68 (12) from diarrhœa and enteritis under two years of age, and 20 (2) from influenza The figures in parentheses are those for London itself

WORK OF HOSPITAL SATURDAY FUNDS—Birmingham Hospital Saturday Fund is about to enlarge Tyn-y-Coed, the Fund's convalescent home for men at Llanrhos, which claims to have been the first convalescent home of its kind in the world Since 1892 when Tyn-y-Coed was opened, more than 107,000 patients have passed through the Fund's five homes, and there are 252 cases waiting for admission at Llanrhos Last year the Birmingham Hospital Saturday Fund exceeded £62,000, and there is now only one large firm in the city which stands outside it—The Leicester and County Saturday Hospital Society is about to build at a cost of between £25,000 and £30 000, a convalescent home for children at Woodhouse Eaves, on the edge of Charnwood Forest During the 23 years of the society's existence it has raised £156 000 for the Leicester Royal Infirmary and convalescent homes and more than 25,000 patients have received free convalescent treatment

Medical News.

UNIVERSITY OF CAMBRIDGE—At a congregation held on July 29th the following degrees were conferred:—

M D—J Rickman and *F A. Barker
M B and B Ch—J W Hope Simpson, K G Salmon P E. Bardsley R. S Starkey, J D M. Stewart, and D P Marks
M.B—F W Roques
B Ch—*L. G Higgins, T F Fox, G G Holmes, F G Winterton A. W Spence, *B C Tate, V B Wigglesworth, and J H Hannan.

* M R C S diploma previously conferred

The undermentioned diplomas have also been conferred —

Diploma in Public Health

E G Anthonisz, C M Brown, Lily C Butler, C K Cullen, P. P. Daruvala, E F Duck, E James, J V Landau, Janet M. MacKay, Catherine J Maclaren, R. C Mahajan, J A Struthers, T Tennent, W D R Thompson, Cicely Weatherall, and M J Whelton.

Diploma in Ophthalmic Medicine and Surgery

R A de C Basto, S N Chau, G S Chowdhary, W J L Duncan, K Eweida, S Fraser, D Hardie, S H G Humfrey, R Lang, E H Lim, A M. MacGillivray, A McGlashan, E G Mackie, M S Mahmood, M C Mason, H B Owen, T G W Parry, W L Peacock, T Pearson, H Rai, P R S Rao, G P N Richardson, F W Robertson, Nina L D Robertson, W J Roche, K G W Saunders, H Singh S G Sorabji, T C Taik, H K Tucker, M L Watts, and L E J Werner

Diploma in Psychological Medicine.

G W J MacKay, J R A Madgwick, J T H Madill, A R Martin, L Minski, and A C Sinclair

Diploma in Laryngology and Otology

T A. Clarke, A L Clowes, A O Davy, J D Dhruv, P Garson, W J Macdonald, C S C Prance, M J Quraishi, B T Rao, B D Uberoi, and J R Wheeler,

Royal College of Physicians of London —An ordinary quarterly Comitia of the College was held on July 29th, the President, Sir John Rose Bradford, being in the chair —Dr D R Paterson, Dr G E C Pritchard, and Sir George Buchanan were admitted to the Fellowship The following having passed the required examinations and satisfied the Censors' Board were elected Members, and all but Dr Simpson were admitted —

Janet K Aitken, Julia Bell, Shankar S Bhatnagar, Harold G Bird, Edward R. Boland, William Brockbank, Norman F C Burgess, Vincent M Coates, Daniel T Davies, Durga R. Dhar, Victor W Dix, Helen W Duncan, Chester K Dunstan, Iris M Harmer, Kenneth E Harris, Richard A P Hill, Alfred B Hodgson, John Holmes, John A. Innes, Reginald S Johnson, Edmund B Jones, Alexander H Kirker, Louis Lavine, Terence C Morton, Herbert W Pearson, Edward S Phipson, Cyril J Polson, Dewan H Rai, Thomas P Rees, William A Robb, Hugh A Robertson, John D Rolleston, John W Simpson, Sidney Smith, and George H Wickens

Licences to practise medicine were granted to 176 candidates who had passed the recent examinations and a number of diplomas were granted jointly with the Royal College of Surgeons —A report was received from the examiners for the Murchison Memorial Scholarship, and the scholarship was awarded to Dr C E Newman and *proxime accessit* Dr P. B Wilkinson, both of King's College Hospital.

The following officers were appointed for the ensuing year —

Censors —Dr H Morley Fletcher, Dr Walter Carr, Dr Robert Hutchison, and Dr F J Poynton

Emeritus Treasurer —Sir Dyce Duckworth

Treasurer —Dr Sidney P Phillips

Registrar —Dr Raymond Crawfurd

Harveian Librarian —Dr T H Arnold Chaplin

Assistant Registrar —Dr R O Moon

Members of the Library Committee —Dr F Parkes Weber, Dr H C Cameron, Dr W C Bosanquet, and Dr C J Singer

Curators of the Museum —Dr J Mitchell Bruce, Sir Frederick W Andrewes, Sir Seymour J Sharkey, and Dr William Hunter

Finance Committee —Dr A G Phear, Dr John Fawcett, and Dr J H Thursfield.

Examiners —Chemistry Mr R H A Plimmer and Mr W H Hurtley Physics Mr J H Brinkworth and Mr Sidney Russ Practical Pharmacy Dr Nathan Mutch, Dr Hugh Gainsborough, Dr W J Adie, Dr V J Woolley, and Dr Orlando Inchley Physiology Prof B J Collingwood and Prof Swale Vincent Pathology Sir Frederick Andrewes and Dr Charles Bolton Anatomy Prof. G Elliot Smith Medical Anatomy and Principles and Practice of Medicine Sir Percival Horton Smith Hartley, Dr A. G Phear, Dr W C Bosanquet, Dr C R Box, Dr Herbert S French, Dr J A Nixon, Sir John Charlton Briscoe, Prof F S Langmead, Dr C E Lakin, and Dr J A Torrens Midwifery and Diseases peculiar to Women Dr Cuthbert H J Lockyer, Sir Henry J F Simson, Mr Malcolm Donaldson, F R C S, Dr William Gilliatt, and Dr Stanley Dodd

Examiners in Public Health —Dr J H Ryffel and Dr C Porter

Tropical Medicine —Sir P W Bassett Smith and Sir Leonard Rogers

Ophthalmic Medicine and Surgery —Dr J S Collier

Psychological Medicine —Part I Dr E. D Macnamara Part II Dr R P Smith and Dr C M. Hinds Howell

Laryngology and Otology —Dr D R. Paterson

The President announced that he had appointed Sir William Hale-White to deliver the Harveian Oration in 1927, and that he had awarded the Bisset Hawkins Medal, 1926, to Dr A. T Stanton —A committee was appointed to consider the arrangements that should be made by the College duly to celebrate in 1928 the Tercentenary of the first publication of Harvey's "De Motu Cordis"—A communication was received from the Secretary of the Medical Research Council asking the President to nominate two Fellows to confer with that Council on the question of continuing the issue of *Medical Science Abstracts and Reviews* Lord Dawson and Dr Fawcett were nominated —The President reported to the College communications with the Home Office concerning the barbitone group of drugs —The Registrar reported the following acceptances of appointments Sir Donald MacAlister, as delegate to the Conference of the National Association for the Prevention of Tuberculosis at Glasgow, Dr A. J Hall as delegate at the Celebration of the Coming of Age of the University of Sheffield, Dr H R Spencer as FitzPatrick Lecturer for 1927, Sir J Charlton Briscoe as Lumleian Lecturer for 1927, Dr Charles Bolton as Croonian Lecturer for 1928, Dr F R Fraser as Goulstonian Lecturer for 1927, Dr C G Douglas as Oliver Sharpey Lecturer for 1927, Dr P C Varrier-Jones as Mitchell Lecturer for 1927, Dean Inge as Lloyd Roberts Lecturer for 1926, in place of Prof Arthur Thomson (resigned) The date of the lecture has now been changed to Friday, Nov 19th, at 5 P M —Various reports of committees were received and the report of the Departmental Committee on the University of London was discussed —The President then dissolved the Comitia

Royal College of Surgeons of England —At an ordinary meeting of the Council on July 29th, Sir Berkeley Moynihan, the President, in the chair, the President stated that the vacancy in the Court of Examiners occasioned by the resignation of Mr Herbert S Pendlebury would be filled up at the ordinary meeting of the Council on Dec. 9th Sir Anthony Bowlby, Sir D'Arcy Power, and Mr Sampson Handley were elected members of the Executive Committee of the Imperial Cancer Research Fund The President said that, as arranged with Prof von Eiselsberg, the Lister Memorial Lecture would be delivered at the College on Thursday, July 7th, 1927 He proposed that a reception should be held in the Museum before the lecture, and that the annual election of members of Council should be held on the morning of the same day

Licences in Dental Surgery were conferred upon A. S Akehurst and S C Clouts

Society of Apothecaries of London —At recent examinations the following candidates passed in the undermentioned subjects —

Surgery —A C F Barrow, Edinburgh, A Henkamp, Gottingen and Royal Free Hosp, and R. F Middleton, Birmingham

Medicine.—N H Allen, Guy's Hosp, F W Barton, Middlesex Hosp, T M Beattie, Leeds, W O H Evans, St Mary's Hosp and Bristol, J B Lurie, St Thomas's Hosp, R I Richards, St Bart.'s Hosp, and G E Rowan, St. Thomas's Hosp

Forensic Medicine —C S Forrest, Middlesex Hosp, H S Littlepage, Birmingham, J B Lurie, St Thomas's Hosp, R F Middleton, Birmingham T E Moody Jones, St Bart 's Hosp, A K Rama Chandra, Edinburgh, G E Rowan, St Thomas's Hosp, R. S S Smith, St Bart 's Hosp, and M Stinnesbeck, Freiburg and Royal Free Hosp

Midwifery —A C Banerji, Charing Cross Hosp, H J J Fordham, St Mary's Hosp, D Jacobson, St Bart 's Hosp, V K Samy, Dundee, M T Y Selim, Liverpool, R S S Smith, St Bart 's Hosp, and T de L Walker, King's Coll Hosp

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery. W O H Evans, R F Middleton, and G E Rowan.

London (Royal Free Hospital) School of Medicine for Women —The Council has awarded the following scholarships and bursaries for the session 1926–27 Isabel Thorne Scholarship, H M Brown (Trinity Hall, Southport), St Dunstan's Medical Exhibition, E J Adams Clark (St Paul's Girls' School), Sir Owen Roberts Scholarship, R E Chamings (L S M W), Mabel Sharman Crawford Scholarship, P Farncombe (Godolphin School), Alfred Langton Scholarship, P D Towell (L S M W), Flora Murray Bursary, M M Fenn (L.S M.W), Fanny Butler Scholarship, R B Snow (St Mary's Hospital), and Dr Edith Pechey-Phipson Post-graduate Scholarship, G H Newell, M B, B S

POST-GRADUATE MEDICAL COURSES IN BERLIN —International post-graduate medical courses are to be held in Berlin from Oct 4th to 30th They will be organised jointly under the medical faculty of the Berlin University, the organisation of the Empress Friedrich-House, and the assembly of academical lecturers There will be a course on advances in general medicine with due regard to the latest therapeutics from Oct 4th to 16th , a course in urology from Oct 18th to 30th , and courses in the special departments *of medicine from* Oct 18th to 30th and from Oct. 4th to 30th Further particulars may be had from Kaiserin Friedrich-Haus, Berlin, N W 6, Luisenplatz 2–4

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —A special course in diseases of children is to be given at the Queen's Hospital from August 16th to 28th Both medical and surgical practice will be dealt with by demonstrations, lectures, and operations Tea and a simple lunch will be provided by the staff, and graduates will have access to all parts of the hospital during the course From August 23rd to Sept 4th the Queen Mary's Hospital, Stratford, will give an all-day course for the benefit of those who wish to renew their acquaintance with hospital practice A new pathological department and maternity wards have recently been opened at this hospital Regular courses in obstetrics are now offered at the City of London Maternity Hospital and practical courses in anæsthetics can be arranged on application to the Fellowship In September special courses will be held in diseases of infants, electro-therapy, ophthalmology, orthopædics, and psychological medicine. There will also be an intensive course in medicine, surgery, and the specialties Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary at 1, Wimpole-street, London, W 1

LONDON POST-GRADUATE HOSTEL.—On July 27th Sir William de Courcy Wheeler took the chair at a meeting of the Hostel at the Imperial Hotel, London, when Prof H. Finsterer (Vienna) opened a discussion on operations of the stomach, in which he advocated gastrectomy for all cases of ulcer. It was not altogether fair, he said, to compare the results of gastro-enterostomy with those of gastrectomy, as the former could often be done successfully by any surgeon, whereas gastrectomy should be performed only by experts In their hands it yielded better results than gastro-enterostomy, but if it were universally practised the mortality would increase greatly In his experience the greater the part of the stomach removed the better the ultimate prognosis, he quoted several cases in which success had only been reached after several partial operations, when almost all the organ had been removed. Sir William Wheeler emphasised the importance of the signs as distinct from the complications of carcinoma, and referred to the diagnostic value of a course of arsenic in deciding between carcinoma and anæmia On July 30th Sir George Lenthal Cheatle opened the discussion on the difference between hyperplasia and inflammation, drawing his conclusion from the study of the breast It was possible he said, to have a cell which was potentially malignant yet held in check by the basement membrane , if such a cell were transplanted, rapid malignant growth ensued. Age was important, and what was inflammatory in a tar-worker of 30 was definitely malignant in a man of 50 So-called chronic mastitis was actually hyperplasia of one of the component parts of the gland or its duct He pleaded for systematic examination of all parts of a breast removed for nodular growth owing to the frequent presence of early carcinoma

Details of the next discussion at the hostel will be found in the Medical Diary given in another column.

MILK AND THE PUBLIC HEALTH.—At the annual meeting of the National Veterinary Association of Great Britain and Ireland, held last week in Dublin, there was a discussion on the relations between the milk-supply and the public health. Mr P F Dolan, Chief Veterinary Inspector of Dublin, said that the immediate complete eradication of tuberculosis from milch cows was impracticable on account of the high percentage of animals affected It was possible that by getting rid of the cow with tuberculosis of the udder and of cases of generalised tuberculosis, and by producing the milk under clean conditions, the amount of tubercle bacilli in it would be reduced to a minimum. Mr A. Gofton, Chief Veterinary Officer for Edinburgh said that milk legislation in Great Britain was too drastic and too drastically enforced The tendency to reduce the available supplies and consequently raise the price would have the effect of driving the poorer classes to buy skimmed milk and substitutes that did not contain what children needed. Milk which was to be pasteurised ought to be of good quality Dr M. J Russell, medical officer of health for Dublin, advocated periodical medical inspection of those who handle milk.

AN Order will be issued by the Ministry of Health making notifiable puerperal pyrexia other than that which is already notifiable as puerperal fever.

LONDON HOSPITAL MEDICAL COLLEGE —The entrance Scholarship in Pathology offered to members of the Universities of Oxford and Cambridge has been awarded to Mr G E Lewis, of Christ's College, Cambridge.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE —Dr R M. Morris has been awarded a Lalcaca Medal in addition to that gained by Dr R Crawford, these two students having obtained an equal percentage of marks in the school examinations of 1926

THE offices of the Panel Committee for the County of London were removed on August 3rd from Staple House, 51–52, Chancery-lane, W C 2. to 17–18, Russell-square, W C 1. Pending the installation of a telephone at the new premises, urgent inquiries may be made to Museum 4464

LISTER CENTENARY CELEBRATION —The centenary year of Lord Lister's birth will be celebrated in Edinburgh in July, 1927, during the meeting of the British Medical Association. The committee responsible for the celebration are anxious to interest students and young graduates in the significance of Lister's work, and they offer a prize of a gold medal and £25 for the best essay on the Influence of Lister on the Evolution of Surgery. Registered students and graduates of not more than one year's standing of any medical school of the British Empire are eligible to submit essays, which must be written in English and must not exceed 10 000 words in length. They should be typed on one side of paper only, and must be sent by May 1st, 1927, to Prof. J Fraser, Convener of the Lister Memorial Committee, 32, Moray-place, Edinburgh. The award of the prize will be made at the Lister Celebration Meeting, July, 1927.

POISONS AND PHARMACY ACTS —As already announced in THE LANCET (July 24th, p 208), a committee has been appointed to consider and report whether any modifications are necessary or desirable in the Poisons and Pharmacy Acts (1) In regard to the conditions relating to the sale of poisons (2) in regard to the procedure for the modification or extension of the Schedule of Poisons to which the Acts apply ; (3) in the system of making and enforcing regulations in regard to the keeping, selling, and dispensing of poisons , (4) in regard to the Central Authority for the purposes of the Acts ; and (5) in regard to any other matters to which the attention of the committee may be drawn. Any person, association. or firm wishing to give evidence or place their views before the committee should communicate as soon as possible with Mr M D Perrins (Joint Secretary), Home Office, Whitehall, S W 1 The committee will inquire generally into the existing machinery regulating the sale (retail and wholesale), keeping, distribution, and supply of poisons any consideration of proposals for the inclusion in or exclusion from the Schedule of Poisons of any specific substance is *not* held to fall within the committee's terms of reference

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.—The seventh annual general meeting of this Society was held on July 28th, Dr J H. Sequeira being in the chair. A resolution was unanimously carried urging the Government "*to grant facilities to the* Venereal Disease Act, 1917, Amendment Bill in view of the support that it has received from the British Social Hygiene Council and the Society for the Prevention of Venereal Disease and the medical Members of the House of Commons" The Chairman suggested that the society should adopt as its motto Sir George Newman's statement that "The first duty of medicine is not to cure disease but to prevent it." The attention of the meeting was drawn to the lately published report on the Health of the Army for 1924, which records a remarkable fall in the incidence of venereal disease during the last four years—a fall which the report attributes to the advance made in prevention, diagnosis, and treatment and to vigorous propaganda. Mr. H. Wansey Bayly, the hon secretary, gave a detailed resume of the Society's work during the past year and said that " not only in this country, but throughout the civilised world there are indications that there has developed an appreciation of the danger of neglect of the venereal menace and a recognition that education in immediate self-disinfection is one of the important means of meeting this drain on the health, industry, and purse of nations and individuals" Mr Basil Peto M.P , was elected President of the Society, and said that all the medical Members of Parliament with one exception, and many lay Members of all political parties, had promised their support to a Bill to amend the Venereal Disease Act, 1917, so as to permit the sale by chemists of approved disinfectants, accompanied by approved printed instructions as recommended in the report of Lord Trevethin's Committee of Inquiry Mr Harry Machin the hon. treasurer emphasised the need for public financial support of the Society

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Rural Housing Bill

On Wednesday, July 28th, Mr **Neville Chamberlain**, Minister of Health, presented in the House of Commons a Bill "to promote the provision of housing accommodation for agricultural workers and for persons whose economic condition is substantially the same as that of such workers and the improvement of such accommodation by authorising the giving of financial assistance towards the reconstruction and improvement of houses and other buildings" The Bill was read a first time

Factories Bill

Sir W **Joynson-Hicks**, Home Secretary, presented in the House of Commons on Monday, August 2nd, the Factories No 2 Bill, a measure to consolidate with amendments the enactments relating to factories The Bill was read a first time

Midwives and Maternity Homes Bill

On Monday, August 2nd, Sir **Kingsley Wood** (Parliamentary Secretary to the Ministry of Health) moved that the House doth agree with the new clause inserted in the House of Lords giving power to exempt certain institutions from Part II of the Bill The motion was agreed to Subsequent amendments inserted in the Bill by the House of Lords were also agreed to

Vivisection

On Tuesday, August 3rd, Lieut -Commander **Kenworthy** presented a petition signed by 1109 persons in Barrow-in-Furness, 142 in Bromley, 980 in Chiswick, 646 in Eastbourne, 648 in Nottingham, 251 in Rochester, and 400 in Tunbridge Wells praying that the practice of vivisection be prohibited by law

Lead Paint Poisoning

On Tuesday, August 3rd, the House considered the Lead Paint (Protection against Poisoning) Bill, as amended in Standing Committee The Bill was read a third time

---

HOUSE OF COMMONS

Wednesday, July 28th

Public Health in Scotland

On the report of a vote of £3,680,342 for public education in Scotland,

Mr **Westwood** moved to reduce the vote by £100 He said he wished to raise the question of the feeding of children during the coal mining dispute Several education authorities in Scotland refused to feed the children during the holidays, and it was rather regrettable that in some instances the lead in this matter had been taken by ministers of the Gospel There had been some doubt in the minds of the education authorities as to their power to feed children during the holidays At least one local authority and certain parish councils had asked for the opinion of the Dean of the Faculty of Advocates The Dean had given it as his opinion that not only had the authorities such power, but that it was their duty to feed the children during the holidays He believed that there was an earnest desire on the part of the Secretary for Scotland and the Under Secretary to see that there was no unnecessary suffering to the people during this great industrial struggle, but he appealed to them to see that all the authorities in Scotland did their duty in this connexion

The **Lord Advocate** said that he found himself quite unable to agree with the opinion of the Dean of the Faculty of Advocates as to the obligation or power of the education authority to feed necessitous school-children during the holidays The relief which it was the duty of parish councils to provide in respect of a child might not necessarily be the same as the relief in the shape of meals which an education authority was to provide under the Act of 1908 The education authority's duty arose where they found a child was not in a condition owing to lack of food or clothing to take full advantage of the education course It would be seen at once by those who were familiar with the Poor-law that there might be cases in which there was a duty on the parish council to provide relief in respect of a child, although the child would still be perfectly capable of receiving and taking in proper education, and, therefore, the two cases did not necessarily meet It might be that parish councils had not carried out their duty, and then, of course, the education authorities might have discovered a case of a child arriving at school improperly fed, but neglect of administration did not alter the construction of the Statute Of course, circumstances might arise which would alter cases He would demur from the legal point of view to this habit of education authorities passing general resolutions that they were not going to deal with a certain class of case with regard to school feeding It was the duty of the education authority to deal with each case individually, and not to say that they were going to grant relief in this or that class of case That was a misapprehension of their duty

Dr **Shiels** said the Lord Advocate seemed to indicate that the legal position was that parish councils were responsible for feeding the children, and only in the event of their failing to do so should the education authorities take action While that might be the legal position, he thought they ought to reflect that here were two public bodies each having the power of feeding children of school age Personally, he would much prefer that the education authority should feed such children and that the Poor law should be kept out of it altogether, if possible Where communal feeding in the school was given the actual expense to the ratepayers was much less He trusted that whatever the legal position the education authorities would continue to be empowered to feed children of school age

Sir **John Gilmour**, Secretary for Scotland, said there was nothing to prevent coöperation between the education authorities and the parish councils in this matter, and arrangements could very often be made more economically after consultation so that the actual feeding should take place at the school There ought, however, to be no alteration in the carrying out of the law in the terms in which the Lord Advocate had explained it, and the responsibilities of the parish council ought to be fully accepted

The motion to reduce the vote was negatived and the vote was agreed to

On the report of a vote of £1,858,345 for the salaries and expenses of the Scottish Board of Health, expenses of administration under the National Insurance Acts, &c ,

Mr **Johnston** moved the reduction of the vote by £100 He said that the position of housing in Scotland was rendered doubly unsatisfactory because of the hesitancy of the Government in informing the municipalities exactly what form of subsidy they were likely to have in October next Everything was being held up They required 20,000 houses per annum in Scotland, but they were getting less than 8000 In Dundee 11 3 of the population lived more than three persons to one room There were 4000 houses where the people were living more than three to one room They had 4000 persons living in houses which had been officially scheduled as unfit for human habitation, and they had 1000 families living in a share of a room—two or more families for one room—and the Prime Minister himself, when he visited the city, expressed himself as horrified with the conditions which he saw there The medical officer of health had urged a great development in house building If the Government withdrew the subsidy and threw them back on what was falsely called "an economic rent" that meant according to figures worked out by the sanitary inspector in Dundee that this alleged economic rent would be £1 per week for a working-class house Who was to pay this £1 per week ? The wages of many workers were such that they could not possibly pay such a rent. He suggested as a means of getting cheaper houses in Scotland that the municipalities should be encouraged to set up municipal banks and that they should be allowed to set the unemployed to work making building materials By these means the Secretary for Scotland could double the output of houses in Scotland , but he could not do it by stopping the subsidy If he stopped the subsidy he simply sentenced hundreds of thousands of people to an early death

Mr **James Barr** said that in the report of the Scottish Board of Health reference was made to the Hospital Services (Scotland) Committee presided over by Lord Mackenzie That report revealed a very alarming state of things in regard to public health in Scotland and in regard to the inadequacy of hospital services For example, medically the hospital accommodation was exceedingly inadequate That meant for all requiring hospital treatment the prolonging of their suffering, for some it meant that they were obliged to wait until it was much too late for them to have any chance of recovery, and for many it meant that they died before admission to the hospital could be secured He admitted that much had been done in regard to hospital accommodation In 1841 in Glasgow 17 per 1000 of the population were admitted to hospital, but in 1924 the figure had risen to 44 9 But when they examined the waiting lists at these hospitals as revealed in the report they found that there were often more people on the list than there were beds in the hospital If they took the six teaching hospitals, as they were called, in the four principal cities of Scotland they found that they contained 3250 beds and that there was a waiting list of 5854 It was true that the waiting lists had to be sifted, but there still remained the fact that the Committee calculated that there was need for 3600 new beds in Scotland to meet the urgent demands of sick people There was the greatest dearth of hospitals for incurables There were only eight such institutions with 602 beds

The children's hospitals in Glasgow, Edinburgh, and Aberdeen were also declared by the Committee to be inadequate The Poor-law hospitals were in many cases carried on in buildings that were originally constructed not as hospitals but as workhouses or for the housing of the poor While they had in Glasgow some splendid hospitals conducted by the parish council authorities, on the whole they suffered very greatly in equipment and buildings which were inferior in every way

In the Minority Report of the Poor-law Commission in 1909 it was asserted that two-thirds of the sick poor were being tended in what were really workhouses, although they were called hospitals Another important point was the stigma of the Poor-law which attached to the sick poor He was glad that the report recommended the transfer of the Poor-law hospitals to the general system of hospitals and that the very best treatment should be given to the poorest people The hospitals under the local authorities were confined to certain specific diseases, but the list of diseases had been expanded and now amounted to 37 In regard to certain forms of disease, such as pulmonary tuberculosis, the Committee thought that with the schemes which were in view, as well as those which now existed, there was sufficient accommodation for the present In regard to other forms of disease such as non-pulmonary tuberculosis, the Committee believed that there was great inadequacy and great urgency He believed that the whole responsibility should be thrown upon the local authorities in a new way and the whole system broadened out. As to finance the Committee calculated that to provide 3600 beds a sum of £1,800,000 would be required, of which they recommended that half should be met by a State grant It appeared to him to be pathetic that these hospitals should depend upon appeals of a varied character, on street collections, and on appeals to the gambling instinct He hoped that the Government were looking forward to a much more comprehensive scheme by which the very best treatment would be given to all without distinction. Considering the inadequacy of the medical equipment he thought it was remarkable that so much had been done. They found, for example, that last year's death-rate for Scotland was 13 4, or 1 per cent. less than in 1924 The infantile death-rate was 90 5, a figure which had only been twice reached in Scotland—in 1921 and in 1923 The death-rate for boys and girls under 5 years was down to 12, a figure which he thought had only once before been touched in Scotland. The pulmonary tuberculosis rate was down to 76, which he believed was a record not only for Scotland but for the United Kingdom, and the non-pulmonary rate was down to 34 Social reformers could take great heart, hope, and courage from a long-stretched consideration of the way in which the death-rate had been brought down. In 1855, a normal year in Glasgow, the annual death-rate was 32 per 1000 now it was down to 13 25 The infantile death-rate in 1860 a normal year in Glasgow, was 182, and now it was 101, and for the whole of Scotland it was less than one-half of what it was in 1860 in Glasgow But a great deal remained to be done

It was significant to look at the death-rates of other countries although they had to bear in mind certain considerations such as differences of climate and the like, but he thought that it was far more due to advance in sanitary and medical service The death-rate in Sweden was 11 4 Norway 11 14 Canada 9 8, and in New Zealand 8 29 If they took the infantile death-rate, which stood in Scotland at 90 5, they found that in Sweden it was 56 in Norway 50 66, and in New Zealand 40 23 In Glasgow there was an enormous disparity between one ward and another For example the death-rate in Cathcart was 9 33 and in Mile End 17 93 The infantile death-rate was 27 in Langside 31 in Cathcart, and 137 in Mile End Last year in Mile End it was 162 To further the interest of public health they have to seek to equalise the social conditions in a city and thus they would save a multitude from death. Housing reform would be a most effective means of improving health and diminishing the death-rate According to the report of the Royal Commission on the Housing of the Industrial Classes in Scotland 1917, on the basis of the census of 1911 it was found that the death-rate among boys under 5 years in one-roomed houses was 30 56 in two-roomed houses 30 2, in three-roomed houses 17 9 and in houses of four rooms and upwards 10 27 They were advancing because of a new mental attitude towards disease—a recognition that it was not inevitable, and was not a part of a providential system of the world The Labour party desired to see the whole health service made a public service and the best medical skill available to all persons without distinction. The health of a nation was its greatest asset.

Brigadier-General **CHARTERIS** said that Mr Barr had given statistics of progress in meeting health requirements which were highly satisfactory But it seemed to him that however greatly they might try to meet the requirements of an ever-growing population they would fall short of doing all that was necessary unless they could take some steps to restrict unnecessary immigration from other parts of the kingdom into Scotland. The result was that the available housing accommodation was hard pressed and there was an adverse influence on public health. He hoped that the Secretary for Scotland would give this matter the close attention it deserved

Mr T **KENNEDY** raised the question of the future of health insurance administration in Scotland through the local insurance committees The whole of the public health administration on this side, he said, was in the melting-pot, and they were very near important changes and far-reaching developments. The Royal Commission had made reference in its report to the status, work and future of these committees and definitely recommended that the local committees should cease to function at an early date and that their work should be transferred to some appropriate municipal or county committee That proposal was made on the ground that there was need for a concentration of local health administration. The committees were charged with responsibility for the arrangement of health insurance benefit and for inquiries into complaints by insured persons, and they organised health lectures and health propaganda generally. This part of their work would have been even more extensive if the committees had had more funds at their disposal In view of these facts he thought that they should seriously consider before they agreed to abolish these committees The matter was being considered by the Scottish Office and the Ministry of Health, but no indication had been given of what action the Government proposed to take in regard to it. He would be very sorry to see Scotland dragged at the tail of England in this matter Scotland ought to adopt its own policy as it had done on medical matters relating to insurance administration. He believed that the approved societies were almost universally opposed to this new recommendation. If the unification pleaded for by the Royal Commission was to be applied on grounds of administrative economy, and it could be proved that it would lead to more efficient management, he would not be prepared to oppose rigidly a new departure on that line. But if any departure was to be made it should not merely take the form of abolishing the present insurance committees and vesting their powers and duties in a public committee, but they ought to make the health service a completely public service maintained out of public money

Mr **BUCHANAN** said he wished to raise the question of venereal disease and also the treatment of the blind. He wished to urge on the Scottish Office the need for more rapid expansion in the treatment of venereal disease. He understood that medical attention in Glasgow and Edinburgh, for instance, was not sufficient to give sufferers from that disease the treatment which they ought to get In Glasgow it was not uncommon to have between 30 and 40 cases in a night and persons who were not given attention very often did not apply again He hoped that the Secretary for Scotland would spend a little time and money in equipping these hospitals both from the surgical and medical point of view with nurses and doctors and also appliances for the treatment of the disease In connexion with blind persons he would ask if the Secretary for Scotland could not take action on their behalf According to the annual report of the Scottish Board of Health a consultative committee had been set up representing the various interests—the blind societies the local authorities education, and municipal. How often was that committee called together? He had had complaints that it had not met frequently enough during the past year Another complaint he had was that throughout Scotland, with Dundee as a bright exception, there was a long waiting list of blind persons anxious to receive training which they could not get. He hoped that economy would not be allowed to stand in the way of the welfare of the blind

Dr **SHIELS** said he wished to raise the questions of light treatment for tuberculosis and for child welfare and rickets He would be glad if the Scottish Board of Health would encourage local authorities to go in for the installation of artificial sunlight because in regard to surgical tuberculosis rickets, and general debility the results had been very remarkable He quite agreed with the criticism of the Board that this was not to be regarded as a panacea for all ills, but he thought that its scope would be more and more extended, and that it would ultimately become one of the most useful therapeutic agents With regard to the new milk legislation he would like to ask the Under Secretary what he thought of the nomenclature of the present graded milk sold under license from the Board of Health He had found that a great many people thought that Grade A milk was the best standard of milk whereas it was only the third standard, and it was possible for Grade A milk to be actually tuberculous The Certified milk was the first quality and the Grade A Tuberculin-tested the second quality He suggested that simply to describe the qualities as A, B, and C or something of that kind would be very much simpler for the public With regard to the medical inspection of school-children they had practically 50,000 children who had been certified as being insufficiently nourished and about 1300 who were certified as being very much under nourished That was a condition of affairs in Scotland which was very unsatisfactory and ought to make them ashamed He would also draw attention to the large number of children who were suffering from enlargement of tonsils, especially in connexion with the later chapter in the report in regard to rheumatic fever They knew that tonsils in a bad condition were a frequent cause of rheumatic fever—one of the most disabling of diseases and one which was of great economic importance

Major ELLIOT, Under Secretary to the Scottish Board of Health, replying to the debate, said that the difficulties in regard to housing were still great, but there was no doubt that progress was being made He agreed that the future of the local insurance committees could not be settled by the *obiter dictum* of the Royal Commission and that a strong case would have to be made out before the Government consented to the abolition of the committees With regard to the Hospitals Report he would call attention to the very specific declaration made by his right hon friend in the last debate on this vote to the effect that the Board of Health were taking this matter into their closest scrutiny and hoped in course of time to make considerable developments in the direction of providing an increased number of beds With regard to venereal disease he agreed that the Broomielaw centre in Glasgow was not entirely satisfactory Further building was going on there, however, and they hoped considerably to improve the situation The International Convention with respect to venereal disease had recently been ratified and in future the disease would be dealt with in accordance with the terms of the Convention He thought that he might say on behalf of the Secretary for Scotland and H M Government that the question of the abolition of the housing subsidy was not being considered by the Government at the present time

The motion to reduce the vote was rejected by 315 votes to 129 and the vote was agreed to

Pay of Naval Sick Berth Ratings

Mr HORE-BELISHA asked the First Lord of the Admiralty whether, in view of the Government decision to give effect to the recommendations of the committee appointed to consider questions relating to pay and other matters affecting recruitment of officers and nurses to the medical branches of the fighting services, he would state if the sick berth staff would benefit by these recommendations, seeing that they were a definite part of the nursing section of the Navy —Mr DAVIDSON, Parliamentary Secretary to the Admiralty, replied The terms of reference of the committee did not include consideration of the sick berth ratings and the reply is therefore in the negative

New Sick Berth Staff Quarters at Plymouth

Mr HORE-BELISHA asked the First Lord of the Admiralty when it was proposed that the sick berth staff should occupy their newly built quarters at the Royal Naval Hospital, Plymouth, which were completed over three months ago —Mr DAVIDSON replied The new quarters are expected to be occupied very shortly

Opium in India

Mr SCURR asked the Under Secretary of State for India whether the Government of India proposed to introduce further legislation against opium smoking in clubs and dens —Earl WINTERTON replied This is a provincial subject The Legislative Councils of the Punjab and of the United Provinces have passed Acts prohibiting opium smoking assemblies of three or more persons, and of two or more persons respectively The Government of Assam contemplate introducing similar legislation

Coroners' Courts in India

Mr SCURR asked the Under Secretary of State for India whether it was the intention of the Government of India to establish coroners' courts in the principal cities of India similar to that established in Bombay, and to cease the conducting of inquests by the police authority —Earl WINTERTON replied There is a coroner also in Calcutta In other parts of India an inquest is not necessarily held by a police officer Magistrates of certain classes have power to hold inquests and do hold them. The law is contained in Sections 174 to 176 of the Code of Criminal Procedure, 1898 I know of no proposal to change it

Cancer Research

Colonel DAY asked the Minister of Health the amount of money expended during the last three years, from public funds, in connexion with cancer research work —Mr NEVILLE CHAMBERLAIN replied The expenditure from public funds directly assignable to cancer research during the three years ending March 31st, 1926, amounted to approximately £20,000, in addition to the use of a stock of radium worth £50,000, which is the property of the Government This figure does not include any portion of the salaries of permanent officers of the Ministry of Health who are engaged in this work, nor does it take account of the cost, not readily estimated separately, of the work upon cancer undertaken by the scientific staff of the Medical Research Council at the National Institute for Medical Research The Council's expenditure upon research in the more primary parts of the medical sciences which is as necessary for the solution of the cancer problem as the direct study of the disease itself, has also materially advanced the knowledge of the subject

Feeding of Necessitous School-children

Mr TINKER asked the President of the Board of Education the number of local authorities who had put into operation the feeding of necessitous school-children, how many had commenced since the coal mining dispute started, and how many children were being fed under this scheme at present.—Lord E PERCY replied During the week ended July 17th, 1926, the latest date for which complete returns are available, 157 authorities were exercising their powers to provide meals, and 258,670 children were being fed Forty authorities have started to provide meals since the coal stoppage began

Silicosis Among Miners

Mr WILFRID PALING asked the Secretary for Mines the number of mine workers reported as suffering from silicosis in each of the years from 1915 to 1925 inclusive —Colonel LANE-FOX Silicosis among mine workers is not a disease required to be reported, and detailed information is, therefore, not available, but the number of cases is known to be small, and so far as coal miners are concerned is almost negligible

Office Sanitation

Viscount SANDON asked the Minister of Health whether he had yet arranged for a test case to be tried as to the powers of local authorities with regard to office sanitation, and, if not, if he intended to do so this year —Mr NEVILLE CHAMBERLAIN replied I cannot myself arrange for a test case to be tried, but I hope that it may be found possible through the initiative of local authorities to obtain a decision in the near future

Unknown Disease at Poplar

Viscount SANDON asked the Minister of Health whether he would publish the results as soon as available of the medical investigations into the recent unknown epidemic in Poplar, and whether he would take all possible steps to secure its elucidation —Mr NEVILLE CHAMBERLAIN replied All possible steps have been taken to elucidate the cause of this outbreak Bacteriological investigations are being continued, but so far have yielded no positive result If and when a conclusion has been reached as to the nature of the outbreak I shall be glad to have the information published

Board of Control and Lunacy Certification

Mr R RICHARDSON asked the Minister of Health if he was aware that a communication was recently sent to the Board of Control by a bench of magistrates commenting on the lack of a proper scrutiny exercised by that Board into the grounds upon which persons were committed to asylums, instancing the case of a Mrs Mary de Freville who was committed last month on a doctor's certificate to Gloucester county asylum, placed in a padded cell, and, when examined by the doctor in charge, sent home as perfectly sane, and, in view of the fact that the Board had itself admitted in its report for 1923 that 22 cases committed in the previous year were found to be sane on admission, would he give directions that certification in all these cases should be declared invalid and their names erased from the roll of lunatics, in order to protect them from the detriment attaching to the stigma of lunacy —Mr NEVILLE CHAMBERLAIN replied Mrs de Freville was admitted to the Goucester Mental Hospital on the 9th ultimo on the authority of an order made by a Justice of the Peace Copies of the reception documents were received by the Board of Control on the 14th ultimo with an intimation that the patient had been discharged on the 11th, the medical superintendent being of opinion that she was not then of unsound mind There is no question of any lack of proper scrutiny by the Board, because the patient was, in fact, discharged three days before the documents reached the Board I should, however, state that in the opinion of the Board the facts observed by the certifying doctor at the time of his examination appear to have afforded ample ground for the conclusion that the patient was at the time of unsound mind and in need of care and control With regard to the latter part of the question, it is erroneous to assume because symptoms of insanity are not found on admission that, therefore, these symptoms were not present at the time of certification and that the patient was improperly certified It is not possible to invalidate the certification of the persons referred to in the question. They were sent to mental hospitals under proper legal authority and on discharge their names were removed from the list of certified patients I appreciate however that some amendment of the law may be desirable to facilitate the provisional observation and treatment, without full certification. of doubtful or transitory cases of mental disturbance and this will be considered in connexion with the recommendations of the Royal Commission whose report has just been issued.

Lead Poisoning in the Potteries.

Mr. Rhys Davies asked the Home Secretary the number of persons suffering from lead poisoning in the potteries in 1925 and in the first half of 1926 · how many were men and how many women; and how many of these cases were among workers who should have been covered by the special regulations of 1913 designed to protect them against lead poisoning —Sir W. Joynson-Hicks replied: The number of cases for 1925 was 47, of which 24 were male and 23 female workers For the first half of 1926 there were 28 cases —14 of either sex. All these workers were employed in processes to which the regulations of 1913 apply.

The University of London Bill.

Dr Little asked the Prime Minister if the University of London Bill [Lords] would be taken before the adjournment for the summer recess —Mr. Baldwin replied. I am afraid I see no propsect of making progress with this Bill before the recess

MONDAY, AUGUST 2ND

Women Factory Workers in Bombay

Mr Robert Young asked the Under Secretary of State for India the number of factory women workers in the Bombay presidency whether there were any women factory inspectors · if so how many; and when these were appointed —Earl Winterton replied · The number of women workers in factories was 72 679 in 1924. One lady inspector was appointed in that year

Outcrop Workers and Health Insurance

Mr Wragg asked the Minister of Health whether the men employed on outcrop mining had their health insurance cards regularly stamped.—Sir Kingsley Wood replied: Insurance cards are required to be stamped for men so engaged if they are employed under a contract of service but not otherwise. If my hon. friend will give me particulars of any case which he may have in mind, I will have inquiries made.

Protection of Civilians Against Gas in Warfare.

Mr Ammon asked the Prime Minister whether a gas mask sufficiently reliable to resist the newest discoveries in gases for use in warfare had been invented; and what steps the Government proposed to take to bring such to the attention of the civilian population and to provide instruction in the use of such protective measures —Mr. Baldwin replied: There is every reason to believe that protective measures are keeping abreast of current developments in gas warfare.

Inspection of Foreign Meat Carcasses

Sir Douglas Newton asked the Minister of Health whether he proposed to seek powers to inspect bacon factories and carcasses purchased by them from abroad.—Mr. Neville Chamberlain replied Officers of local authorities already have powers under the Public Health Acts to enter bacon factories and inspect all carcasses found therein. I may add that all carcasses imported into this country are liable to inspection at the port of entry

Lead Poisoning in the Potteries

Mr Rhys Davies asked the Home Secretary whether he was aware that there had been cases recently in the potteries where young girls had suffered from attacks of lead poisoning similar to those which were frequent before the introduction of the 1913 special regulations · whether he could account for these cases and what steps he intended to take to enforce the regulations with a view of stamping out the disease —Sir W. Joynson-Hicks replied I find that during the last 18 months there have been three reported cases of lead poisoning among girls under 21 employed in the potteries All three cases I am glad to say were slight I regret it has not been possible to ascertain definitely how these attacks arose The most careful attention is paid to the enforcement of the regulations but so far as the factory inspector could discover, none of these cases was due to any breach of the regulations or to any defect in the working of the process

TUESDAY AUGUST 3RD

Venereal Disease in the Army

Mr Basil Peto asked the Secretary of State for War whether he would see that in the next report on the health of the Army the figures relating to the incidence of venereal disease were brought up to date and that a report would be included as to the effect of preventive and other measures taken to reduce it —Sir L. Worthington-Evans replied · As regards the first part of the question the statistics relating to diseases in the Army cannot be compiled until the information is received from all Commands, both at home and abroad which in the case of India is not until July of the year following that to which they refer. It is hoped that the report for 1925 will be ready for publication by the end of the current year. As regards the second part of the question reference to page 17 of the report for the year 1924 will show that reference is already made to the effect of preventive and other measures.

Fatal Accidents in the Mining Industry

Lieut -Colonel Heneage asked the Secretary of Mines the number of fatal accidents in the mining industry of Great Britain per 10 000 men for 1922–23 1923–24 and 1924–25 · and if he could obtain similar figures for the Russian mines —Colonel Lane-Fox replied: The number of separate fatal accidents in the mining industry of Great Britain was at the rate of 9 per 10 000 persons employed in 1923. 1924 and 1925 At Russian mines the corresponding numbers were eight in the year ended September, 1924, and ten in the following year. Particulars for 1922–23 are not available.

Miners and Silicosis

Mr Wilfrid Paling asked the Secretary for Mines whether any cases of silicosis had been reported which were alleged to have been caused through operating the stone-dusting regulations applying to coal mines.—Colonel Lane-Fox replied The allegation has occasionally been made, but every case in which it has been made it has proved on investigation not to be silicosis.

Accidents to Pedestrians in London.

Mr Campbell asked the Minister of Transport whether there had been any and, if so, how many, accidents to pedestrians as a result of the roundabout system of traffic in various parts of London.—Sir W. Joynson-Hicks replied: I will circulate a statement of the number of accidents to pedestrians which have occurred so far as known to the police at each of the places where the system has been introduced, but it is impossible to say whether any and, if so how many of these accidents have occurred as the result of the introduction of this system. I am glad to say none of the accidents has been fatal. The statement referred to gives the number of accidents to pedestrians at places where the gyratory system of traffic regulation is in force. The figures given in each case apply from the date of institution of the system to July 27th, 1926, inclusive:—

Place.	Date of institution of gyratory system.	No of accidents
Parliament-square ..	Jan. 4th, 1926	16
Queen Victoria Memorial .	Jan. 25th ,,	4
Hyde Park Corner .	March 22nd ,,	13
Aldwych .	Oct. 12th ,,	8
Trafalgar-square .	April 26th ,,	11
Piccadilly-circus ..	July 26th ,,	—
King-street, Hammersmith	,, 26th ,,	—
		52

Cost of Poor-law Relief

Sir Frederic Wise asked the Chancellor of the Exchequer the total amount paid in Poor-law relief in England and Wales for 1925 and from Jan. 1st to March 31st, 1926, and from April 1st to June 30th 1926 —Sir Kingsley Wood replied Figures for indoor relief during the periods mentioned are not yet available The total amounts of domiciliary Poor-law relief given in money and kind in England and Wales were —

In the year ending	December 1925	£14 550,356
,, quarter	March 1926	£4,123,738
,, ,, ,,	June, 1926 (approx.)	£5,545,000

Lunacy Law Reform

Mr Robert Richardson asked the Minister of Health if his attention had been drawn to the recent decision in the Court of Appeal in the case tried in April last of Harnett v Fisher from which it resulted that if any sane person was wrongfully shut up in an asylum for six years he was debarred from redress and would he at an early date initiate legislation to remove this.—Sir Kingsley Wood replied · My right hon. friend is advised that the deduction which the hon Member draws from the decision of the court in this case is too wide As regards legislation, my right hon. friend can add nothing to the answer given on May 3rd beyond saying that he has under consideration the recent report of the Royal Commission on Lunacy Law and Administration.

Relief to Miners' Wives and Children

Mr Rhys Davies asked the Minister of Health whether he was aware that the Bolton board of guardians had decided to continue their refusal to grant outdoor relief to miners wives and children one of the grounds being that a decision of the board could not be altered for six months after the date of such decision · and whether he would intervene in such a way as to remove this obstacle to a change in the board's policy if they so desired —Sir KINGSLEY WOOD replied Yes, Sir My right hon friend is aware of the decision of the Bolton guardians and that a motion for its rescission which was fully discussed and rejected by 27 votes to 15 on July 14th, was ruled out of order on the ground suggested on July 28th It is not in his power to intervene in the manner suggested, but he has no doubt that if the majority of the board desired to alter the present decision, some way would be found of dealing with any difficulty arising from their standing orders

The Services.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Bruton (Somerset), Earsdon (Northumberland), Horsham (Sussex), Hollingbourne (Kent), Newport (Isle of Wight), and at Hanley (Staffs)

Births, Marriages, and Deaths.

BIRTHS

ALLISON —On July 27th, at Harlaw, Hope terrace, Edinburgh, the wife of Dr John Allison, Jun, Kettering, of a daughter

WILSON —On July 29th, the wife of Dr H Lydiard Wilson, Gordon-square, of a son

MARRIAGES

BLORE—YOUNG —On July 28th, at the Parish Church, Halesowen, W Roy Blore, M C, M B, B S Lond., to Margaret, daughter of Dr and Mrs Brett Young, of Halesowen, Worcs

GRIPPER—SYMONS —On July 28th, at Salisbury Cathedral, Captain Geoffrey Dawson Gripper, R A M C, to Sylvia Clare, second daughter of the late Colonel F A Symons, C M G, D S O, A M S, and Mrs Symons, of De Vaux Lodge, Salisbury

PLATT—HERON WATSON —On July 28th, at All Souls', Langham place, W, Lieut -Commander Francis Cuthbert Platt, D S O, R N, to Francis Heron-Watson, M B, D P H, elder daughter of Charles Heron-Watson, The Croft, Longforgan, Perthshire

TOOP—TRESILIAN —On July 27th, at St Andrew's Church, Enfield, Bernard Miall Toop, M.R C S, L R C P, to Nora Mabel, younger daughter of the late F J Tresilian, M D, F R C P, and Mrs Tresilian, of White Lodge, Enfield

WALLACE—COUTTS —On July 31st, at St Peter's Church, Norbiton, Herbert Kelvin Wallace, M R C S, L R C P L D S, to Marjorie, elder daughter of Dr Francis J H Coutts, C B, and Mrs Coutts, of Kingston Hill

DEATHS

HUNT —On July 26th, suddenly, Lieut -Colonel Rochford Noel Hunt, D S O, R A M C, of Belgrave road, Eccleston square, S W, aged 53

McVAIL.—On July 29th, at Nethway, Torquay, John Christie McVail, LL D, M D, D P H, in his 77th year

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages and Deaths

Medical Diary.

Montgomery Lecture

ON THE

CLINICAL USE OF THE SLIT-LAMP.*

Delivered at Trinity College, Dublin,

BY T HARRISON BUTLER, M D OXF,
SURGEON, BIRMINGHAM EYE HOSPITAL, HON OPHTHALMIC SURGEON, COVENTRY AND LEAMINGTON GENERAL HOSPITALS

IT is fitting that I allude to the founder of this lecture Dr Montgomery was a member of the staff of the Royal Victoria Eye and Ear Hospital A man of quiet, unassuming demeanour, he was wholly devoted to his work By his legacy he conferred a lasting benefit upon ophthalmology, and we may feel certain that the slit-lamp would have given him the greatest pleasure

ADVANTAGES OF THE INSTRUMENT.

The introduction of the ophthalmoscope heralded the opening of a new era in ophthalmology, fruitful in discovery regarding the anatomy and pathology of the eye Still something was wanting The ophthalmoscope deals with two dimensions in space, and the older methods of focal illumination were inadequate to supply the third dimension, our measurements of depth, our localisation along the axis of the eye, were at best good guessing In 1912 Gullstrand invented the first slit-lamp and incidentally supplied the third dimension The original slit-lamp was improved and associated with the corneal microscope by Henker Vogt added the adjustable slit which gave the "optical section" The slit-lamp and corneal microscope, as made by Zeiss, allow us to localise along the optical axis of the eye, without the use of any academic methods, within a limit of 1/5th of a millimetre The Czapski-Zeiss microscope is provided with Ulbrich's micrometer drum, divided into tenths of a millimetre, and measures the travel of the instrument from one focus to another. With this we can gauge the depth of the anterior chamber or the thickness of the lens with fair accuracy The micrometer eye-piece allows us to make transverse measurements, and when it is used with a goniometer, which registers the angle between the visual and illuminating axes, accurate estimations of depth can be made This method is somewhat academic and is unnecessary for routine clinical work The chief advantage gained by the slit-lamp is the optical section, one that we cannot overvalue; but there are others An ordinary loupe magnifies about six times, the corneal microscope offers a stereoscopic view of the eye as far back as the anterior third of the vitreous, giving a magnification of 35 With an exceptionally steady patient we can fit a higher eye-piece and obtain 60 diameters Personally, I think 35 quite sufficient, and I find that I obtain no advantage by using a strong eye-piece Magnification by high-powered oculars is a cheap and nasty way of failing to attain the desired result As Koeppe[1] says, "the resolution of the finer details of the observed tissue is essentially a function of the numerical aperture of the objective employed, and independent of the ocular magnification"

The beam of the Zeiss slit-lamp is under the most perfect control It can be freely moved independently of the microscope up, down, right, left, and focused upon any desired spot This allows us to use varieties of illumination and to change them automatically as occasion may dictate By throwing the beam of light slightly out of focus we obtain a diffuse illumination which is often of value The beam may be brought to an exact focus upon any given structure and gives direct focal illumination We can focus it upon a reflecting surface behind the object under review and use transillumination or retro-illumination. Thus we examine the cornea by light reflected from the iris in lens-light We can illuminate the cornea by a pencil of light reflected from the posterior lens capsule and make out fine changes which are difficult to detect by other means (These methods are illustrated in Fig 1) It is often useful to take advantage of mirror light to work in the zone of specular reflection Instead of avoiding the mirror of the light from the cornea or lens capsules, we deliberately use these dazzling zones, and are able to see on the anterior corneal surface deposits of fine drops and fine irregularities, on the posterior surface the endothelial cells, on the anterior lens capsule the shagreen and the epithelial cells, and finally the posterior shagreen We can easily understand the advantages of the specular zone if we take an ophthalmoscope case and hold it in relation to a bright light in such wise that we get the direct reflection of the light back to our eye We notice at once how the details of the shagreen of the leather spring into prominence In some cases the reflection from a surface such as the iris is so intense that detail is lost By focusing the light somewhat laterally we see our object by scattered light, by indirect lateral illumination This form of lighting is specially used to see the sphincter of the iris

FIG 1

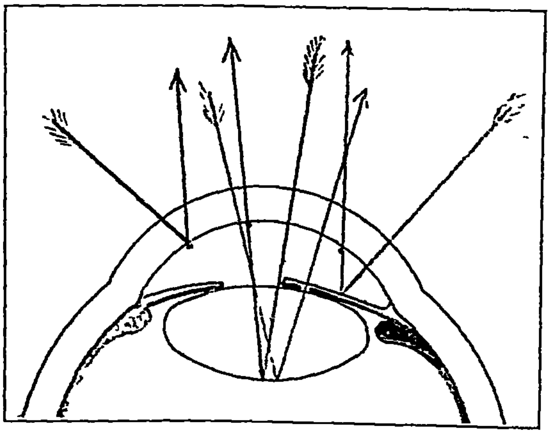

Diagram illustrating direct focal illumination of an object on the back of the cornea, retro illumination of a similar object from the iris and from the posterior capsule of the lens, and retro illumination of a hole in the retinal layer of the iris by lens light

Another method of illumination has been called scleral scatter by Graves If we bring the beam to a focus upon the limbus we at once notice a glow all round the cornea, brightest directly opposite the spot of light The light is reflected backwards and forwards between the anterior and posterior surfaces of the cornea till it reaches the sclera, and in its passage it illuminates the corneal substance; the structure becomes relucent, to use another apt word coined by Graves A tenuous opacity in the cornea may be seen against the internal glow when it is almost invisible by other forms of illumination

The last available method is illumination by fundus light Light directed against the sclera penetrates and is reflected back from the fundus Fissures in the retinal layer of the iris glow blood-red in fundus light It is obvious that to take full advantage of these methods which are used instinctively and alternately by the expert, the lamp-arm must move absolutely independently of the microscope If, for example, we are examining keratic precipitates (K P.) we light them alternately by direct focal and retro-illumination Some objects, such as the fine filaments which cross the retrolental space, uniting the lens to the vitreous, can be seen only by oscillatory light.

intervene in such a way as to remove this obstacle to a change in the board's policy if they so desired —Sir KINGSLEY WOOD replied Yes, Sir My right hon friend is aware of the decision of the Bolton guardians and that a motion for its rescission which was fully discussed and rejected by 27 votes to 15 on July 14th, was ruled out of order on the ground suggested on July 28th It is not in his power to intervene in the manner suggested, but he has no doubt that if the majority of the board desired to alter the present decision, some way would be found of dealing with any difficulty arising from their standing orders

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Comdrs to be Surg Capts T B Shaw, P L. Crosbie, C K Bushe, and T W Myles

Surg Lt-Comdr M B Macleod to be Surg Comdr

Surg Lt W J McB Allan to be Surg Lt-Comdr

ROYAL NAVAL VOLUNTEER RESERVE

Surg Comdr R Wilbond has been awarded the Royal Naval Volunteer Reserve Officers' Decoration

ROYAL ARMY MEDICAL CORPS

Bt Col W R P Goodwin to be Asst. Dir-Gen

F Widlake to be Temp Lt

The undermentioned retire on retd pay and are granted the rank of Lt-Col Majs F L Bradish and E J Kavanagh

Maj D T MacCarthy retires on retd pay

Maj T W O Sexton to be Maj whilst empld under Article 507 (*b*), Royal Warrant for Pay and Promotion, 1926.

TERRITORIAL ARMY.

Lt G B Tait to be Capt

Capt K V Bailey, late Manch R, to be Lt. and relinquishes the rank of Capt.

2nd Lt H R Paterson, late R F A, to be Lt

Hygiene Companies 2nd Lt D Lamont, late R G A, T F, to be Lt

ROYAL AIR FORCE

J Twohill is granted a short service commission as a Flying Officer for three years on the active list

INDIAN MEDICAL SERVICES

Maj R E U Newman officiates as Assistant Director of Hygiene and Pathology, Western Command, vice Maj J W Houston Maj J G Gill has been appointed Deputy Assistant Director of Hygiene, Central Provinces District, vice Maj G P Taylor, deceased, and Maj C A Wood has been appointed Deputy Assistant Director of Medical Services, Southern Command, vice Maj W E R Williams, vacated Capt R D Davy officiates as Deputy Assistant Director of Medical Services (Embarkation) at Karachi, vice Maj P G M Elvery, Capt S Nag officiates as Specialist in Surgery at Jappulpore, vice Capt D J Batterham, and Maj P M Rennie has been posted as Civil Surgeon, Amraoti Capt E R Daboo has handed over charge of the Jorhat Jail to Maj H L Batra, civil surgeon, Sibsagar Dr K B Dustur on return from leave has resumed his appointment as Medical Officer of Health, Agra Lt-Col F P Warwick, civil surgeon, Amraoti, and Dr Y. B Ranade, deputy, have been granted leave

Appointments.

DUKE-ELDER, W S, M D St And, F R C S Eng, has been appointed Assistant Ophthalmic Surgeon to St George's Hospital, London

FREW, W D, M R C S, L R C P Lond, to be one of the Medical Referees under the Workmen's Compensation Act for the Kilmarnock District

SIMPSON, HAROLD C, L M S S A, D P H, Assistant County Medical Officer of Health for Cumberland

Montgomery Lecture

ON THE

CLINICAL USE OF THE SLIT-LAMP *

Delivered at Trinity College, Dublin,

By T HARRISON BUTLER, M.D. Oxf ,

SURGEON, BIRMINGHAM EYE HOSPITAL, HON OPHTHALMIC SURGEON, COVENTRY AND LEAMINGTON GENERAL HOSPITALS

It is fitting that I allude to the founder of this lecture Dr Montgomery was a member of the staff of the Royal Victoria Eye and Ear Hospital A man of quiet, unassuming demeanour, he was wholly devoted to his work By his legacy he conferred a lasting benefit upon ophthalmology, and we may feel certain that the slit-lamp would have given him the greatest pleasure

Advantages of the Instrument.

The introduction of the ophthalmoscope heralded the opening of a new era in ophthalmology, fruitful in discovery regarding the anatomy and pathology of the eye Still something was wanting The ophthalmoscope deals with two dimensions in space and the older methods of focal illumination were inadequate to supply the third dimension, our measurements of depth, our localisation along the axis of the eye, were at best good guessing In 1912 Gullstrand invented the first slit-lamp and incidentally supplied the third dimension The original slit-lamp was improved and associated with the corneal microscope by Henker Vogt added the adjustable slit which gave the "optical section" The slit-lamp and corneal microscope, as made by Zeiss, allow us to localise along the optical axis of the eye, without the use of any academic methods, within a limit of 1/5th of a millimetre The Czapski-Zeiss microscope is provided with Ulbrich's micrometer drum, divided into tenths of a millimetre, and measures the travel of the instrument from one focus to another With this we can gauge the depth of the anterior chamber or the thickness of the lens with fair accuracy The micrometer eye-piece allows us to make transverse measurements, and when it is used with a goniometer, which registers the angle between the visual and illuminating axes, accurate estimations of depth can be made This method is somewhat academic and is unnecessary for routine clinical work. The chief advantage gained by the slit-lamp is the optical section, one that we cannot overvalue, but there are others An ordinary loupe magnifies about six times, the corneal microscope offers a stereoscopic view of the eye as far back as the anterior third of the vitreous, giving a magnification of 35 With an exceptionally steady patient we can fit a higher eye-piece and obtain 60 diameters Personally, I think 35 quite sufficient, and I find that I obtain no advantage by using a strong eye-piece Magnification by high-powered oculars is a cheap and nasty way of failing to attain the desired result As Koeppe[1] says, "the resolution of the finer details of the observed tissue is essentially a function of the numerical aperture of the objective employed, and independent of the ocular magnification"

The beam of the Zeiss slit-lamp is under the most perfect control It can be freely moved independently of the microscope up, down, right, left, and focused upon any desired spot This allows us to use varieties of illumination and to change them automatically as occasion may dictate By throwing the beam of light slightly out of focus we obtain a diffuse illumination which is often of value The beam may be brought to an exact focus upon any given structure and gives direct focal illumination We can focus it upon a reflecting surface behind the object under review and use transillumination or retro-illumination. Thus we examine the cornea by light reflected from the iris in lens-light We can illuminate the cornea by a pencil of light reflected from the posterior lens capsule and make out fine changes which are difficult to detect by other means (These methods are illustrated in Fig 1) It is often useful to take advantage of mirror light to work in the zone of specular reflection Instead of avoiding the mirror of the light from the cornea or lens capsules, we deliberately use these dazzling zones, and are able to see on the anterior corneal surface deposits of fine drops and fine irregularities, on the posterior surface the endothelial cells, on the anterior lens capsule the shagreen and the epithelial cells, and finally the posterior shagreen We can easily understand the advantages of the specular zone if we take an ophthalmoscope case and hold it in relation to a bright light in such wise that we get the direct reflection of the light back to our eye We notice at once how the details of the shagreen of the leather spring into prominence In some cases the reflection from a surface such as the iris is so intense that detail is lost By focusing the light somewhat laterally we see our object by scattered light, by indirect lateral illumination This form of lighting is specially used to see the sphincter of the iris

Fig 1.

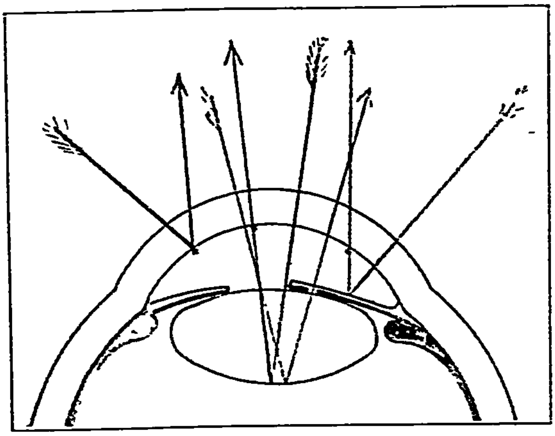

Diagram illustrating direct focal illumination of an object on the back of the cornea, retro-illumination of a similar object from the iris and from the posterior capsule of the lens and retro illumination of a hole in the retinal layer of the iris by lens light

Another method of illumination has been called scleral scatter by Graves If we bring the beam to a focus upon the limbus we at once notice a glow all round the cornea, brightest directly opposite the spot of light The light is reflected backwards and forwards between the anterior and posterior surfaces of the cornea till it reaches the sclera, and in its passage it illuminates the corneal substance; the structure becomes relucent, to use another apt word coined by Graves. A tenuous opacity in the cornea may be seen against the internal glow when it is almost invisible by other forms of illumination

The last available method is illumination by fundus light Light directed against the sclera penetrates and is reflected back from the fundus Fissures in the retinal layer of the iris glow blood-red in fundus light. It is obvious that to take full advantage of these methods which are used instinctively and alternately by the expert, the lamp-arm must move absolutely independently of the microscope If, for example, we are examining keratic precipitates (K.P.) we light them alternately by direct focal and retro-illumination Some objects, such as the fine filaments which cross the retrolental space, uniting the lens to the vitreous, can be seen only by oscillatory light.

* Owing to lack of space it is impossible to publish more than a selection of the drawings which illustrated this lecture In consequence the subject matter has been somewhat abridged and modified

[1] American Journal of Ophthalmology, ix , 158.

THE APPARATUS RECOMMENDED.

I advise the use of the Zeiss slit-lamp. It is unwise to have anything to do with the combined slit-lamp and Gullstrand ophthalmoscope. The best lenses to get are paired objectives A 0: A 2: and A 3, ocular 2, and a micrometer ocular. I recommend the objective A 0 instead of F 55. The latter magnifies only nine times, and I regard it as a pretty toy. A 0 is a useful lens, magnifying 15 times. It serves most purposes and is easy to use. It is not powerful enough to see the endothelium in detail or to observe small particles in the aqueous. A 0 has been little used as yet, but I have recently obtained one and I find that I am employing it more than any other. I greatly prefer the glass-top table to the double slides for moving the microscope. This mechanical stage is easier to use, but is a handicap to the expert. Using A 0 and the glass top it is possible to focus the microscope by sliding it on the glass: it can be instantly slewed at will, and the movements of the patient can be followed automatically, for we hold the microscope by the screw which raises and lowers it and so we have complete control with one hand. This is not possible with the mechanical stage.

THE EXAMINATION BY SLIT-LAMP.

A slit-lamp examination falls under two heads, with the broad beam and with the narrow beam.

When a ray of light passes through media in the eye which are not optically homogeneous but composed of lamellæ, some of the light is internally reflected and dispersed, and the medium glows: it becomes relucent. Optically homogeneous media remain dark. Thus the cornea, the lens, and the vitreous become relucent, whereas the epithelial layer of the cornea, the aqueous, and the retrolental space, remain almost dark. I say almost, for an optically inactive medium does not exist in the eye. The appearance when the narrow beam is thrown into the eye is seen in Fig. 2. To the left we see a scimitar-like crescent of light, the section of the relucent cornea. The adjacent dark area is the anterior chamber. The lens is on the right and shows areas of optical discontinuity. To the extreme right we may note the faint glow of the vitreous. Careful focusing will allow us to make out the architecture of the vitreous, which in section shows as a series of sinuous waving bright lines, the edges of the membranes which compose the organised part of the vitreous. In most slit-lamp drawings the whole structure is shown in sharp focus, but in reality this is not the case. This figure shows the optical section of the eye, the organ is seen in profile: we have gained our third dimension.

In Fig. 3 we see the effect of throwing the broad beam into the eye. A block of light is seen in the area of the cornea, the *prisma* in German. Although it is not a geometrical prism, it is convenient to use the word prism to describe this relucent block. The cortical layer of the lens forms a second prism. The lens prism is not so sharp as the corneal and the posterior surface is more strongly curved than the anterior. It is very important to differentiate this prism, because its posterior surface is the face of the adult nucleus, a landmark in the lental landscape. Behind the prism we generally see the posterior inverted Y, another prominent landmark marking the posterior surface of the embryonic nucleus of the lens. The anterior erect Y is generally very difficult to detect.

We can now pass on to a more detailed study of the eye as seen with the slit-lamp, taking the structures in anatomical sequence.

THE CORNEA.

The corneal prism is shown in Fig. 4. The surface to the left is the epithelial surface of the cornea, the darker surface to the right marks the margin of the beam of light—we call it the proximal section. There is a distal section, but this is invisible. Looking through the prism we focus upon the endothelial surface of the prism. This reflects light faintly, and in the young normal cornea is not obvious. In the aged, and after interstitial keratitis the endothelial surface reflects light strongly and stands out clearly as a somewhat opaque granular surface. It is possible to see the epithelial layer of the cornea; if we over-run our lamp, using a voltage of 10 instead of the usual 8, and focus sharply upon the extreme distal edge of the epithelial surface of the prism we see a clear layer—this is the optically inactive epithelial layer of the cornea.

Reverting to the normal prism as shown in Fig 4 we note that the stroma is granular in appearance. In the outer two-thirds of the prism the corneal nerves are seen. At the periphery they are thick and medullated, but as they enter the transparent cornea they lose their medulla, and look like threads of cotton. They divide dichotomously and occasionally show a web-like formation in the angle between two twigs. We see no trace of Bowman's tubules or of Recklinghausen's canals. Leber has shown that these structures are artefacts. Koeppe, using magnifications of 60 and 80, has described an elaborate system of lymph passages, but his observations have not received confirmation.

If we examine the endothelial surface of the cornea in the zone of specular reflection we see a yellow shagreen area, which on careful focusing resolves itself into a mosaic of hexagonal cells, the endothelial layer of the cornea. Among the cells there are dark crater-like formations. These may in part correspond to the Hassal-Henle warts, thickenings of Descemet's membrane. In the pig's eye the endothelial cells are very large and their nuclei are seen as dark dots in the centre of the cell. In man the nuclei are held to be invisible, but we recently examined a miner and found that his endothelial cells were abnormally large, and we were able to see the nuclei distinctly. Bowman's and Descemet's membranes are unseen till they fall into folds. Such are very common in Descemet's membrane, and form after operations and accidents which perforate the cornea, and in corneal inflammation and oedema. They are seen in great profusion in interstitial keratitis. The folds may take various forms. After a central keratitis the wrinkles in both Bowman's and Descemet's membrane—fine in the former, coarse in the latter—radiate star-like from the centre towards the periphery of the cornea. Those seen after operations spread from the scar and have a double contour with silvery edges. They rapidly disappear as the healing of the wound progresses.

Ulceration of the cornea can be minutely examined with the slit-lamp. When the beam is thrown on to the ulcer we note a deep notch in the prism, and by moving the beam over the surface of the ulcer we obtain a series of contour lines which supply a complete map of the configuration of the ulcer. We can follow the process of healing and the onset of vascularisation in all its details.

Bullous Keratitis.—In this condition the detachment of the epithelium can be viewed in section, and when the cornea is superficially vascularised we can locate the pannus just under the epithelium.

The Visible Circulation.—If one of the smaller vessels in a pannus or a deep vascularisation be examined by retro-illumination so that the vessel is seen by transmitted light, using the iris as a mirror, the actual circulation of the blood is clearly perceived. Globules are observed coursing along the capillaries. In the very smallest the flow is intermittent as described by Krogh. In others the corpuscles are at intervals propelled along the vessels like shots from a machine-gun. In a small twig joining two larger trunks the flow may be rhythmically reversed. It is most fascinating to watch the phenomena of the circulation with the corneal microscope under the illumination of the slit-lamp. It is probable that the globules we see are the actual corpuscles. In a favourable case the blood stream can be seen with an ordinary loupe with the illumination of a [illegible] lamp.

The Apparatus Recommended.

I advise the use of the Zeiss slit-lamp It is unwise to have anything to do with the combined slit-lamp and Gullstrand ophthalmoscope. The best lenses to get are paired objectives A 0 · A 2 and A 3, ocular 2, and a micrometer ocular I recommend the objective A 0 instead of F 55. The latter magnifies only nine times, and I regard it as a pretty toy A 0 is a useful lens, magnifying 15 times. It serves most purposes and is easy to use It is not powerful enough to see the endothelium in detail or to observe small particles in the aqueous A 0 has been little used as yet, but I have recently obtained one and I find that I am employing it more than any other I greatly prefer the glass-top table to the double slides for moving the microscope. This mechanical stage is easier to use, but is a handicap to the expert Using A 0 and the glass top it is possible to focus the microscope by sliding it on the glass; it can be instantly slewed at will, and the movements of the patient can be followed automatically, for we hold the microscope by the screw which raises and lowers it and so we have complete control with one hand This is not possible with the mechanical stage

The Examination by Slit-Lamp

A slit-lamp examination falls under two heads, with the broad beam and with the narrow beam

When a ray of light passes through media in the eye which are not optically homogeneous but composed of lamellæ, some of the light is internally reflected and dispersed, and the medium glows; it becomes relucent. Optically homogeneous media remain dark Thus the cornea, the lens, and the vitreous become relucent, whereas the epithelial layer of the cornea, the aqueous, and the retrolental space, remain almost dark. I say almost, for an optically inactive medium does not exist in the eye The appearance when the narrow beam is thrown into the eye is seen in Fig. 2. To the left we see a scimitar-like crescent of light, the section of the relucent cornea The adjacent dark area is the anterior chamber. The lens is on the right and shows areas of optical discontinuity. To the extreme right we may note the faint glow of the vitreous Careful focusing will allow us to make out the architecture of the vitreous, which in section shows as a series of sinuous waving bright lines, the edges of the membranes which compose the organised part of the vitreous In most slit-lamp drawings the whole structure is shown in sharp focus, but in reality this is not the case This figure shows the optical section of the eye, the organ is seen in profile; we have gained our third dimension

In Fig 3 we see the effect of throwing the broad beam into the eye A block of light is seen in the area of the cornea, the *prisma* in German Although it is not a geometrical prism, it is convenient to use the word prism to describe this relucent block The cortical layer of the lens forms a second prism The lens prism is not so sharp as the corneal and the posterior surface is more strongly curved than the anterior It is very important to differentiate this prism, because its posterior surface is the face of the adult nucleus, a landmark in the lental landscape Behind the prism we generally see the posterior inverted Y, another prominent landmark marking the posterior surface of the embryonic nucleus of the lens The anterior erect Y is generally very difficult to detect

We can now pass on to a more detailed study of the eye as seen with the slit-lamp, taking the structures in anatomical sequence

The Cornea

The corneal prism is shown in Fig 4. The surface to the left is the epithelial surface of the cornea, the darker surface to the right marks the margin of the beam of light—we call it the proximal section There is a distal section, but this is invisible Looking through the prism we focus upon the endothelial surface of the prism This reflects light faintly, and in the young normal cornea is not obvious In the aged, and after interstitial keratitis, the endothelial surface reflects light strongly and stands out clearly as a somewhat opaque granular surface It is possible to see the epithelial layer of the cornea, if we overrun our lamp, using a voltage of 10 instead of the usual 8, and focus sharply upon the extreme distal edge of the epithelial surface of the prism, we see a clear layer—this is the optically inactive epithelial layer of the cornea

Reverting to the normal prism as shown in Fig 4 we note that the stroma is granular in appearance In the outer two-thirds of the prism the corneal nerves are seen. At the periphery they are thick and medullated, but as they enter the transparent cornea they lose their medulla, and look like threads of cotton. They divide dichotomously and occasionally show a web-like formation in the angle between two twigs We see no trace of Bowman's tubules or of Recklinghausen's canals Leber has shown that these structures are artefacts Koeppe, using magnifications of 60 and 80, has described an elaborate system of lymph passages, but his observations have not received confirmation

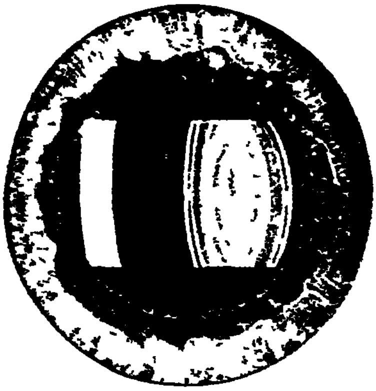
If we examine the endothelial surface of the cornea in the zone of specular reflection we see a yellow shagreen area, which on careful focusing resolves itself into a mosaic of hexagonal cells, the endothelial layer of the cornea Among the cells there are dark crater-like formations These may in part correspond to the Hassal-Henle warts, thickenings, of Descemet's membrane In the pig's eye the endothelial cells are very large and their nuclei are seen as dark dots in the centre of the cell In man the nuclei are held to be invisible, but we recently examined a miner and found that his endothelial cells were abnormally large, and we were able to see the nuclei distinctly Bowman's and Descemet's membranes are unseen till they fall into folds Such are very common in Descemet's membrane, and form after operations and accidents which perforate the cornea, and in corneal inflammation and œdema They are seen in great profusion in interstitial keratitis The folds may take various forms After a central keratitis the wrinkles in both Bowman's and Descemet's membrane—fine in the former, coarse in the latter—radiate star-like from the centre towards the periphery of the cornea Those seen after operations spread from the scar and have a double contour with silvery edges They rapidly disappear as the healing of the wound progresses

Ulceration of the cornea can be minutely examined with the slit-lamp. When the beam is thrown on to the ulcer we note a deep notch in the prism, and by moving the beam over the surface of the ulcer we obtain a series of contour lines which supply a complete map of the configuration of the ulcer We can follow the process of healing and the onset of vascularisation in all its details

Bullous Keratitis—In this condition the detachment of the epithelium can be viewed in section, and when the cornea is superficially vascularised we can locate the pannus just under the epithelium

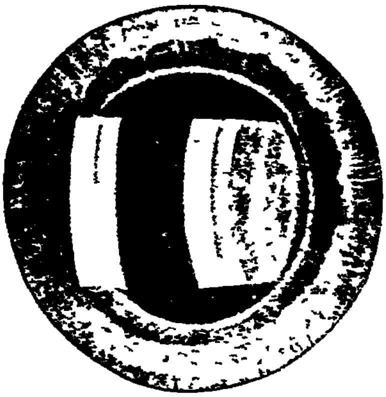
The Visible Circulation—If one of the smaller vessels in a pannus or a deep vascularisation be examined by retro-illumination so that the vessel is seen by transmitted light, using the iris as a mirror, the actual circulation of the blood is clearly perceived Globules are observed coursing along the capillaries In the very smallest the flow is intermittent as described by Krogh In others the corpuscles are at intervals projected along the vessels like shots from a machine-gun In a small twig joining two larger trunks the flow may be rhythmically reversed It is most fascinating to watch the phenomena of the circulation with the corneal microscope under the illumination of the slit-lamp It is probable that the globules we see are the actual corpuscles In a favourable case the blood stream can be seen with an ordinary loupe with the illumination of a half-watt lamp.

FIG. 2



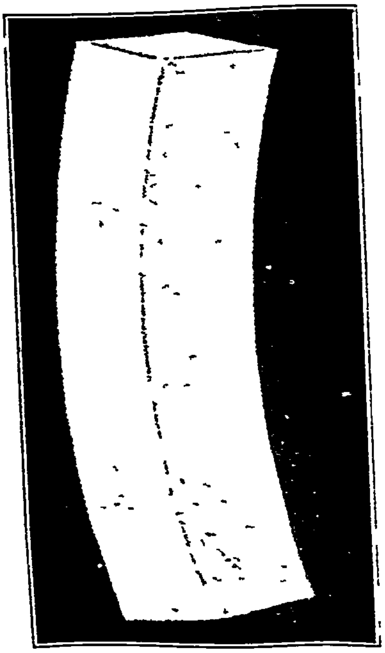
Illumination of the eye by the narrow beam.

FIG 3



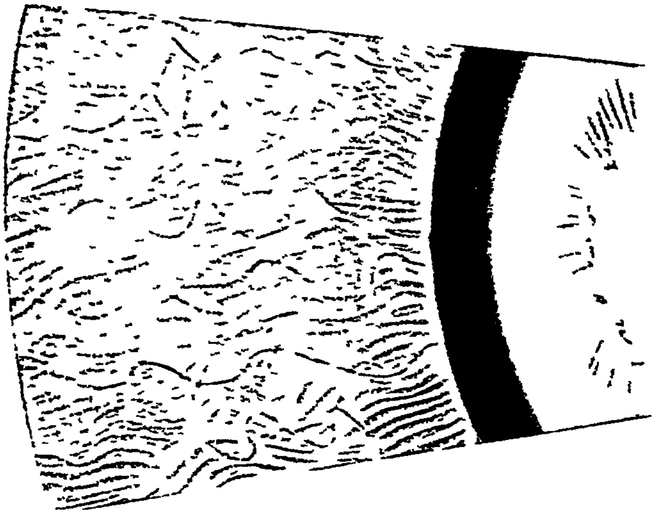
Illumination of the eye by the broad beam.

FIG. 4.



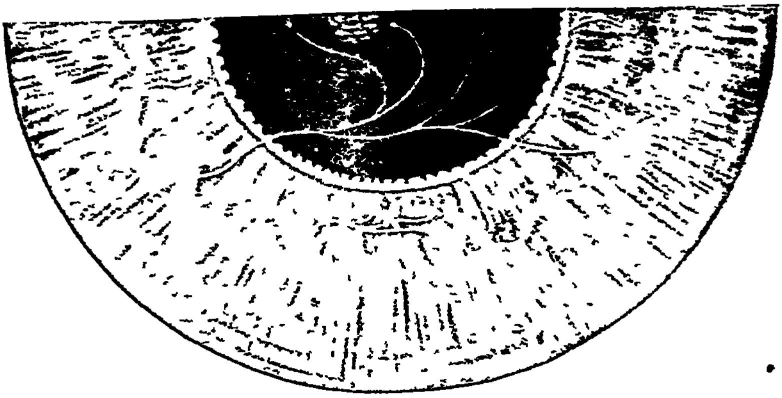
The corneal prism. Light coming from the left shows corneal nerves

FIG. 5.



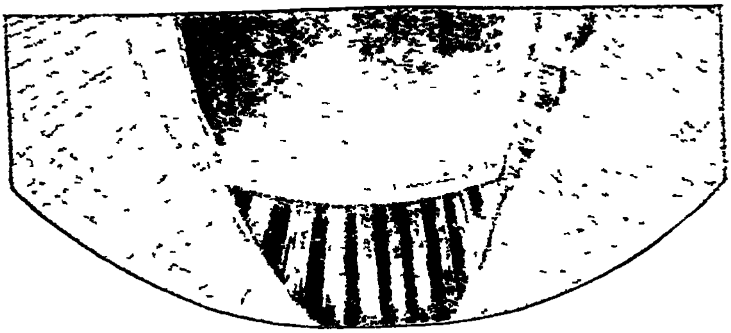
A highly atrophic iris The sphincter is clearly seen Blood vessels of the iris, some of which are functional and others are mere fibrous strands

FIG 6.



A normal iris showing the frill from which arise filaments of the pupillary membrane A few stars on the anterior capsule

FIG. 7.



Congenital coloboma of the iris exposing a normal zonular ligament.

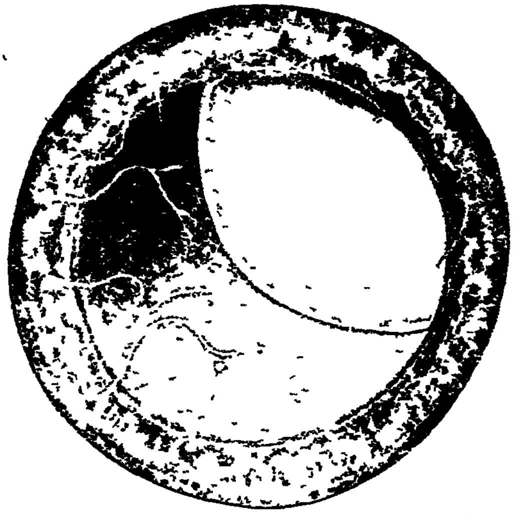
THE IRIS.

The examination of the iris presents no difficulties We must not forget that in a light-coloured iris the mesodermal layers are semi-transparent The surface of the iris can be examined by direct focal or indirect lateral illumination In a blue or atrophic iris the latter method demonstrates the sphincter of the iris The mesodermal layers are composed entirely of blood-vessels with an enormously thick adventitia, joined by loose connective tissue I doubt whether many of these structures are functional, for in an acute iritis only a few of them carry a visible blood stream These vessels are well seen in Fig 5 This represents a highly atrophic iris the result of a chronic irido-cyclitis To the right we see a shrunken lens with a rupture of the capsule through which the cortex is herniating The pigmented margin of the iris has entirely disappeared The sphincter is clearly visible, forming a dark brown zone immediately within the pupil margin The anterior layer of the mesodermic portion has disappeared and the deeper layer is highly atrophic The white strings are the remains of the arteries which form the main structure They are now small in number and sclerosed Among them a few are functioning as blood-carrying vessels Heterochromic cyclitis is another form of iris atrophy which can with advantage be studied with the slit-lamp (Pictures of this condition can be found in illustrations to the Doyne Memorial Lecture) In this disease the posterior retinal layer of the iris is atrophic and eventually disappears over considerable areas When such an iris is examined by light reflected back from the lens the atrophic patches transmit the light which shines through and gives the iris a moth-eaten appearance

THE LENS

Our knowledge of the anatomy and pathology of the lens has been almost revolutionised by the slit-lamp. By its aid we are now able to see it in sharp section and to map it out into zones Seen with the broad beam it is found to have, not two surfaces but several, one within the other, each with special characteristics

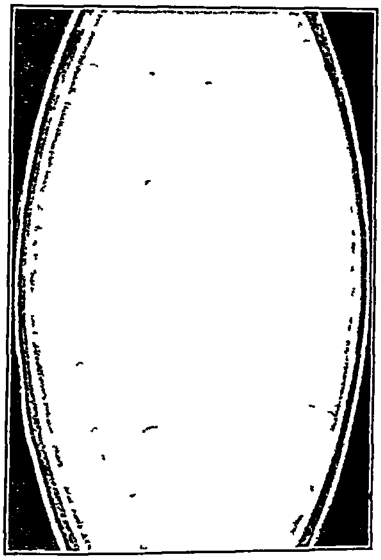
FIG 8



A congenital subluxation of the lens There is no trace of a suspensory ligament Vestigial fibres of the suspensory ligament spring from the frill

The Pupillary Membrane —All ophthalmologists are well acquainted with the anomaly known as persistent pupillary membrane, but till quite recently it was not realised that vestiges of the structure are very common With the loupe we frequently observe a small collection of pigment dots upon the anterior capsule of the lens These are not evidences of a past iritis but vestiges of the tunica vasculosa lentis anterior. Under a magnification of 35 they are seen to be stellate and generally tripolar. The arms of the stars are prolonged as grey fibrils which often anastomose with another star forming a rough network These stars may be infrequent; perhaps one only may be found, or they may form a dense brown film which impedes vision We occasionally see fine cobweb-like threads arising from the iris frill or small circle running across the anterior chamber either to join the frill on the opposite side or to float free in the aqueous These vestiges invariably arise from the frill, and never from the pupil margin The anterior mesenteric leaf of the iris takes little part in the movements of the iris, so these telegraph-like wires remain in tension when the pupil contracts An example of this condition is shown in Fig 6

FIG 9



Lamellar cataract in an adult caused by a cerebral abscess at the age of 13 (The embryonic nucleus has become too distinct in the process of reproduction)

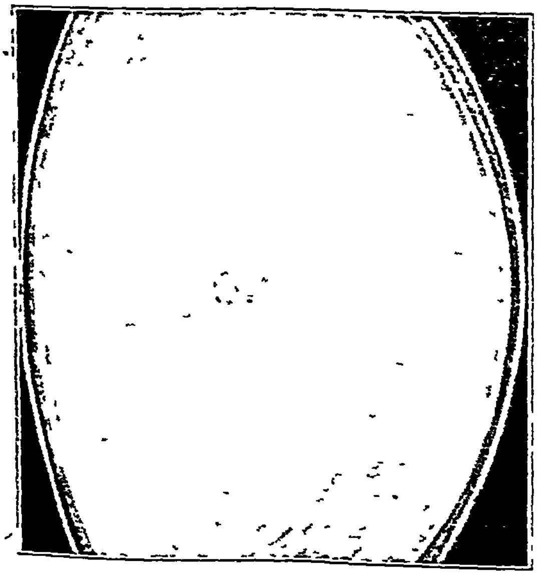
The Suspension of the Lens —The lens is suspended in the eye by the zonule of Zinn just as the hub of a bicycle is hung by the spokes It does not lie upon the vitreous, but is surrounded before and behind by the aqueous humour There is a perilental and a retrolental space both in free communication with the posterior chamber If this arrangement is disturbed, if the anterior chamber is abolished and the lens touches the cornea, its nutrition suffers and nuclear cataract forms I believe that the same is true of the retrolental space, and that the cause of senile nuclear cataract is to be sought in degeneration of the vitreous and disappearance of the retrolental space The zonule of Zinn is a beautiful structure under the corneal microscope The fibres are attached to the lens before and behind at some distance from the equator, and pass back between the ciliary processes to be inserted into the ora serrata and the vitreous This arrangement would incline to draw the lens backwards, but this tendency is neutralised by another set of fibres which pass forward to be attached to the ciliary processes I have seen fibrils taking this direction The main strands, each consisting of about seven fibres, number about 140 and lie in the valley one on each side of a ciliary process The suspensory ligament cannot be seen in the normal eye, but is visible in cases of subluxation and in congenital colobomata of the cornea A drawing of the latter abnormality is shown in Fig 7

Congenital dislocation of the lens is seen in three forms in what we may call the decentred lens the zonule of Zinn is perfect; in the ectopic lens the suspensory ligament is imperfect, and in the subluxated lens it is entirely absent An example of the latter form is shown in Fig 8 Here the lens is displaced and there is no trace of the zonule, but several vestiges of the pupillary membrane are present This classification has not only academic but clinical significance The first kind will not become displaced into the anterior chamber or fall into the vitreous, the last is liable to and will be difficult to extract, wander in the eye and is easier to remove; the third variety occupies an intermediate position.

THE LENS STRUCTURE.

The slit-lamp shows that the lens has a most complicated optical structure. When viewed with the narrow beam it shows a series of concentric lamellæ of varying hue and refringence. These zones of optical discontinuity may be considered from two standpoints. They may represent merely regions of slightly varying refractive index or express definite anatomical areas, dissimilar in physiological properties, reacting differently to toxic influences and to trophic disturbance. Both views are correct. The lens is an epithelial structure and grows constantly throughout life. The epithelial cells lay down fibres layer by layer like the annual rings of a tree. If there has been no modification of nutrition during childhood we should expect a homogeneous lens, and we often find it. The lenses of some children are almost devoid of zones, whereas other children of the same age possess a lens showing a varied landscape. We may reasonably suppose that the life of the first child has been regular and nutrition uniform. The second may have been subject to rhythmic subtle alterations in nutrition which are reflected in the lens. It would be interesting to investigate the history of several children to discover harmony between the lens architecture and alterations in general health. It is certain that under conditions of markedly abnormal nutrition the deposition of the lens fibres is profoundly modified, and we may get zones in which their actual structure is pathological. Lamellar cataract is a condition of this kind associated with general evidence of malnutrition such as tetany and ridged teeth. Similar changes are seen in the finger-nails. I recently examined a patient with lamellar cataract, which is shown in Fig 9. Here the opacity is outside the infantile nucleus, and I dated it as commencing at about 13 years of age. Subsequent inquiry elicited the fact that when 13 years of age the child had suffered from a cerebral abscess with acute ear symptoms. She had had a mastoid operation and had been trephined. She was acutely ill for a long time and in bed for nearly a year.

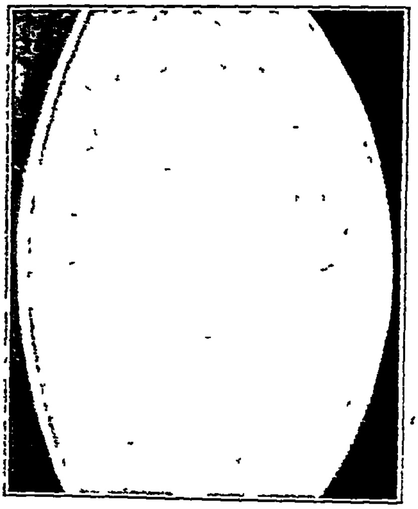
FIG 10.



A typical adult lens of the conventional type. The central axial cataract throwing a shadow backwards is found in 25 per cent of all lenses.

In addition to minor optical zones there are in the lens definite anatomical tracts. Fig 10 illustrates what we may call the Vogt conventional lens; I made the drawing from an actual patient, but such lenses are uncommon. Commencing from without, we first note the capsule, a bright scintillating line bounding the lens figure before and behind. The capsule has a very tenuous outer layer, the zonular lamella, to which the fibres of the zonule are attached. This may be seen with the slit-lamp when it becomes detached. Under the capsule there is a clear zone bounded internally by a well-defined bright non-scintillating line the subcapsular or reduplication line. This line is generally present, but occasionally in the aged and the young it cannot be made out with the ordinary apparatus. The yellowish zone under the subcapsular line we call the cortex. This region is in the adult separated from the central nuclear system by a well-defined surface which in later life reflects light strongly. This is the face of the adult nucleus which appears at about 12 years of age. Within the adult nucleus we have what I prefer to call the infantile nucleus, but which Vogt calls the outer embryonic nucleus. Centrally, we find two plano-convex bodies, the embryonic nuclei. These are separated by a dark space, the central lucid interval. This is the oldest part of the lens and is invariably present. On the posterior surface of the anterior lens of the embryonic nucleus there is an axial opacity which throws a dense shadow backwards. This is almost physiological for it is found in 25 per cent. of all lenses (Vogt). The curvature of the successive zones from without inwards increases up to the infantile nucleus, after which they become concentric. Not only is the curve sharper towards the centre, but in the young there is often a tendency to a reverse curve equatorially. This becomes very obvious in cases of lamellar cataract. Probably this system of curves corrects chromatic aberration and the plano-convex lenses at the centre neutralise spherical aberration. Fig 11 is a child's lens. In this particular example there was no subcapsular line and the adult nucleus had not yet formed. The surface of the infant nucleus divides the lens into cortex and nuclear system. The whole lens tends to be homogeneous and the yellow tinge of the cortex has not appeared. We used the narrow beam to obtain the sectional view of the lens that we have been discussing. With the broad beam we can differentiate the surfaces with their characteristic suture systems.

FIG 11.



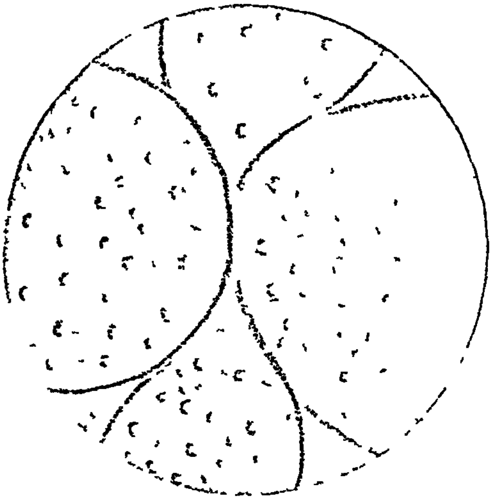
The lens of a child of 6. The posterior inverted Y is seen on the surface of the nucleus. No subcapsular line could be seen in this particular lens.

The *surface of the capsule* showed the shagreen which was well known long before the slit-lamp. It can be seen with the ordinary loupe under appropriate arrangement of illumination. In the shagreen the epithelial cells are seen, and occasionally it is iridescent. Slight iridescence especially when a large surface is seen with the loupe, is physiological, but excessive colour sheen indicates early cataractous changes in the lens. With the loupe we can see the complicated suture system of the cortex.

The *sutures of the adult nucleus*, especially in the aged have a most characteristic appearance which is shown in Fig 12 They are raised cameo-fashion from the surface of the nucleus in front, whereas behind the sutures are seen as an intaglio Often the surface is covered with bosses which may take the place of the sutures, giving a hob-nail boot appearance.

The *primary embryonic sutures of the lens*, the anterior and posterior Y's, characterise the surface of the embryonic nuclei Contrary to what is stated in all the text-books, the anterior Y is erect and the posterior inverted This mistake is curious, for the anterior Y is occasionally in lamellar cataract visible to the naked eye The lens fibres can be seen arising from the Y sutures They start from the tip of one Y and run round to the bifurcation of the other Thus, the fibres take a spiral course, and are all of approximately the same length The two Y's are shown in Figs 13 and 14 If we follow the nasal arm of the posterior Y to its bifurcation we shall see a white ring or part of a ring, often with some granulation or slight pigmentation This is the arc-line (Vogt's *Bogen-Linie*), the situation where the hyaloid arteries were attached to the lens Hanging from the arc-line we see, in most children, the hyaloid artery looking like a spiral piece of thick string In later life this generally falls off leaving a stump The artery is seen in Fig 15 The fundus drawing (Fig 16) shows a persistent hyaloid ending in a mushroom The anterior part of the hyaloid was found to be normal The anterior two-thirds had separated normally from the posterior third which had failed to absorb I am indebted to Miss Ida Mann for the information that the hyaloid normally separates in this situation; the posterior half absorbs, the anterior commonly persists

FIG. 12



The relief sutures of the adult nucleus

CATARACT

If the aqueous contains toxins the capsules and the cortex will suffer first A typical example is naphthaline cataract The posterior capsule is especially prone to be affected by toxic influences In certain cases of low-grade cyclitis and choroiditis the vitreous degenerates and the posterior capsule shows alterations. The most striking evidence of this is pronounced iridescence of the posterior capsule, which shows a mother-of-pearl sheen with sparkling points of metallic lustre This change heralds the advent of cataracta complicata The posterior shagreen is always more lustrous than the anterior, and slight iridescence is not uncommon and is compatible with health Vacuoles form under the capsules They vary in size and shape, and are easily seen with the ophthalmoscope

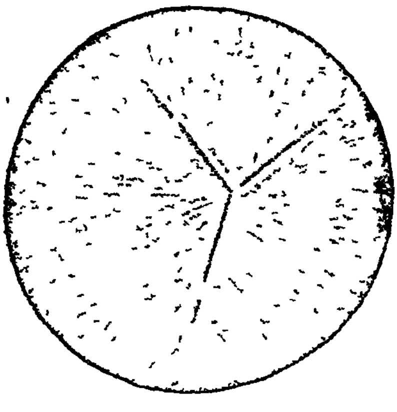
The commonest form of senile cataract takes the form of cortical striæ These spicules are developed in the following manner the cortex begins to split into lamellæ, the *lamellarer Zerklüftung* of Vogt These rifts in the cortex do not follow the path of the lens fibres or of the sutures, but run diagonally across the cortex Seen in section the lamellar separation causes a sort of herring-bone appearance. Comparatively clear spaces filled with fluid now form between the lamellæ, the *Wasser-Spalt* or fluid-cleft These fluid-clefts may enlarge and run together so that a large area of the cortex may become perfectly homogeneous and pellucid in appearance This phenomenon explains those cases of cataract in which a decided improvement of vision takes place Generally, however, the clefts fill up with solid material and form opaque spicules

Fibrillation of the adult nucleus is frequently seen, but in this case the process consists in a separation of the actual fibrils. The adult nucleus is the favourite seat of punctate opacities In cataracta punctata cœrulea these have a blue colour, and are generally associated with club-shaped peripheral opacities, the cataracta coronaria of Vogt This is an acquired cataract and is slowly progressive in some cases In the optical section the opacities are seen to lie in the adult nucleus

The infantile nucleus is the usual situation of lamellar cataract. In this form we get a wreath of artificial scintillating particles giving the appearance of ice A cataract of this type has been shown in Fig 9

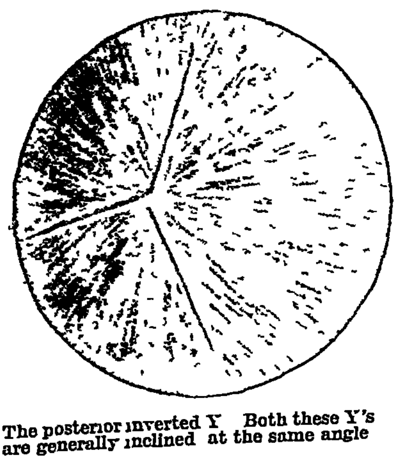
Central cataracts are generally familial A typical example is shown in Fig 17 The central sphere is considerably smaller than the embryonic nucleus, showing that it originated very early in the development

FIG 13



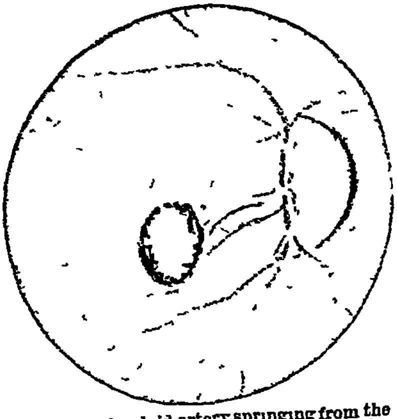
The anterior erect Y showing lens fibres

FIG 14



The posterior inverted Y Both these Y's are generally inclined at the same angle

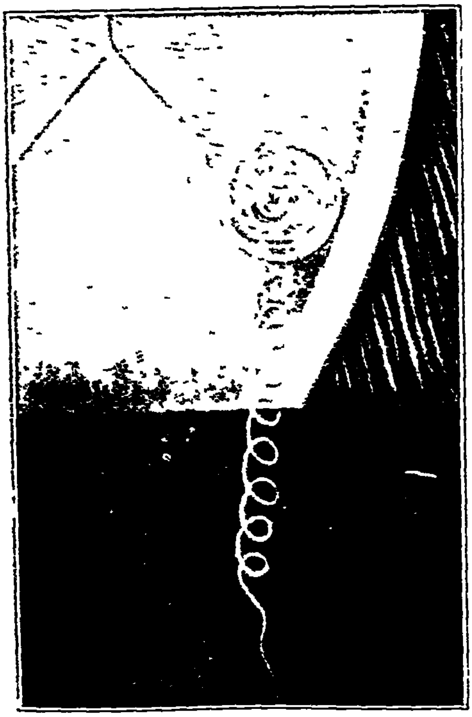
FIG 16



A persistent hyaloid artery springing from the optic nerve head and ending in a disc Anterior part of the same artery is seen in Fig 15 of the lens The sutures are exterior to the confines of the opacity. The drawing shows the view with the loupe and a section made with my pocket slit-lamp

Nuclear cataract begins as an excessive sclerosis of the central portion of the lens. The sclerosed nucleus is always surrounded by a transparent zone and is at first itself transparent. In a typical example the cortex is normal, the clear zone is strongly differentiated and within it we see the sclerosed nucleus, greenish in front, yellowish to brown behind. Later on the nucleus will grow, especially axially; its curvature will increase, and its contour will be less sharp and eventually blurred Finally, its surface may become crenellated This is the condition known to the text-books as myopic degeneration of the lens If the index of refraction should rise in relation to that of the cortex we have the lens with a double focus because the axial portion has a greater dioptric strength than the periphery. Fortunately, the pupil of the aged is small and the actual effect is myopia and sometimes irregular lental astigmatism. Such lenses have been described as suffering from lenticonus posterior. This condition is very rare and is quite a different thing In a more advanced stage of nuclear sclerosis, figured in the Doyne lecture, the cortex was full of fluid-clefts, and there was high-grade sclerosis of the nucleus with increased curvature. Vision with minus 8 was 6/12. The surface of the adult nucleus seen in section gave the impression of an internal capsule It was covered with nodules which appeared in the section as definite knobs Each threw a dense shadow backwards Nuclear sclerosis passes gradually into nuclear cataract if the nucleus becomes opaque Often the bronze colour seen in the early cases deepens and we obtain the brown and black cataracts Nuclear cataracts may rapidly form without passing through the sclerotic stage when the nutrition of the lens suffers, as for example if the anterior chamber is abolished and the lens comes into contact with the cornea.

FIG 15



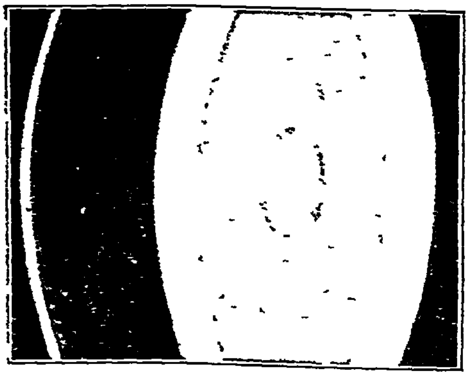
The arc-line and the vestige of the hyaloid artery hanging down in the retrolental space It is found in 75 per cent of all children, but falls off in later life

MEDICO-LEGAL VALUE OF THE SLIT-LAMP.

I can only briefly allude to this subject, which is of immense importance In industrial towns we are frequently called upon to decide whether a fragment of metal which has struck the cornea has actually perforated. In the majority of cases the slit-lamp will at once supply the answer. If we focus the beam upon the scar we are able to decide whether the track of the fragment passes through the cornea by noting that it is visible on the endothelial surface. In a case under our care there was a wound traversing the cornea. An opening was visible in the anterior capsule and a passage could be traced right through the lens ending in a wound of exit in the posterior capsule. Here the cortex was softening and exuding into the retrolental space. This afforded an additional proof that the posterior surface of the lens is bathed in the aqueous which had entered the lens, causing a cataract by dissolving the cortex, just as it does after a discission of the anterior capsule

In another case I had removed a fragment of steel from an eye by the posterior route with the giant magnet. Fortunately, I had made full notes with drawings Perfect recovery took place with full acuity. The patient was not seen for ten years, when he appeared with a cataract in the wounded eye and siderosis The natural conclusion was that there had been two foreign bodies and that one only had been removed, for there was no history of any subsequent accident There was a wound in the iris that did not appear in the original drawings, but this could in a court of law have been put down to defective observation. The slit-lamp at once supplied the correct solution. The original wound was still visible in the cornea but only at an entry and an exit scar. Between the two the corneal substance had become clear. Another penetrating wound was found in the cornea showing a continuous track from front to back. This was a much younger injury and the corneal stroma had not become transparent. It was obvious that this wound and the unrecorded iris wound were recent events, and that there had been two separate perforations of the eye by a fragment of steel. The eye was removed and the fragment found in the vitreous. The cases might have been of great importance had the man been working for two employers, for obviously the first would have had no liability for the second accident

FIG 17.



A familial central cataract. Optical section made with the author's pocket slit-lamp Magnified six times with an ordinary loupe

Many of the drawings shown at the lecture but here omitted are to be found in: The Doyne Memorial Lecture, *British Journal of Ophthalmology*, vol viii p 561; the *Transactions of the Ophthalmological Society*, vol. xliv, p. 57, vol xlv., part 2, p. 657: and the *British Medical Journal*, May 31st, 1924.

THE EXAMINATION OF THE GASTRIC CONTENTS IN INFANTS,

WITH SOME CONSIDERATIONS AS TO THE VALUE OF LACTIC ACID MILK IN INFANT FEEDING

By ETHEL CASSIE, M D, D P H EDIN,
CHIEF MEDICAL OFFICER FOR CHILD WELFARE AND MEDICAL SUPERINTENDENT OF THE CARNEGIE INSTITUTE, BIRMINGHAM,
AND
URSULA COX, M R C S, D.P.H,
ASSISTANT MEDICAL OFFICER FOR CHILD WELFARE, BIRMINGHAM

THIS inquiry was instituted in view of the increased stress laid on the importance of the acidity of the gastric contents in disorders of the digestion in young infants It was felt that it would be of interest to ascertain whether any relationship could be established between the type of milk given, the acidity of the gastric contents, and the clinical symptoms shown by the infant The absence of free HCl in the gastric contents of infants under 1 year, after any type of test-feed, corresponding to a normal feed for such an infant, requires to be made clear, since some authorities have written in such a way as to suggest the presence of free HCl in these cases Free HCl is found in the resting juice, or following the administration of barley water, or a very small feed, but not during the digestion of an adequate meal In many cases 1 oz of sweetened barley water was given at intervals of 3–4 hours after the last feed, and the stomach contents withdrawn 10 minutes later In all cases where no food remained in the stomach free HCl was present, but in those cases where there was delay in emptying, and curd remained in the stomach from the last meal, free HCl was absent We have also found that if a very small feed is given —e g , a 60 c cm feed to a child of 4–6 months—and there is no delay in the emptying of the stomach, so that at the end of an hour only 5–10 c.cm remain, with practically no curd, then free HCl is found Any discrepancy between our results and those of some other observers[1, 2] who have found free HCl at varying periods after a feed may be explained by the size of the feed given All the results quoted in our tables were obtained after a "full" feed—i e , the one-sixth part of a milk mixture considered adequate to the caloric requirements of a child of the given age and weight Keeping these facts in mind, and realising that an appreciable quantity of material must be obtained for satisfactory chemical tests, the methods detailed below were decided on as the most satisfactory for our purpose American workers especially have suggested that the value of lactic acid milk and other acidified milks depends on the higher acidity of the gastric contents obtained with them, but it was felt that very little was known of the normal reaction to the ordinary types of milk used in varying forms of infantile dyspepsia, and that possibly the difficulty in the average case was not due to this factor to any important extent

A very valuable synopsis of the recent literature on this subject has been published in the *American Journal of Diseases of Children* (May and November, 1925) and those interested cannot do better than study these articles It is frequently difficult to obtain access to the American journals in which most of the publications have appeared

The work of Faber[3] and Marriott[4] on the value of acidified milk in infant feeding, considered to be due to the neutralisation of the variation between cow's milk and human milk in buffer content, is fairly well known, though acidified milk has not yet been used to any great extent in this country as compared with America Faber has shown that gastric lipase is fully active at a pH of 4 5 and 4 0, while pepsin acts from pH 5 0 but does not reach its full activity till pH 2 3 This last figure implies the presence of free HCl and is very rarely, if ever, reached in the infant's stomach during normal digestion In order to obtain a pH concentration of 4 5 much more acid secretion is required for cow's milk than for human milk owing to the higher buffer content due to phosphates and calcium caseinate. Faber and Marriott believe that the difficulty of successful feeding with cow's milk is due essentially to this factor and can be overcome by the use of acid milks, whether hydrochloric acid or lactic acid be used, and both observers use milk little if at all diluted, and with a high fat percentage, Faber using HCl in preference to lactic acid milk Marriott adds carbohydrate in the form of corn syrup Lactic acid milk can be used from birth, but hydrochloric acid milk is not recommended till after the sixth week While the value of acidified milk feeding in certain cases is not disputed, it was felt that the results obtained were possibly not due to the change in the pH concentration only, but that other factors were coming into play In souring the milk a light flocculent curd is obtained, and it is necessary to break this up before administering the milk to the infant, therefore an actual change in the physical quality of the milk is present as well as a chemical change, and this may be of considerable importance Excellent results have been obtained in several cases at the Carnegie Institute by simply curdling milk lightly with rennet, breaking up the curd, and giving this to the infant In the average infant's stomach very little remains at the end of two hours, so much was this found to be the case that the test-meals were usually removed at the end of one hour There is, then, no doubt that ordinarily the bulk of digestion takes place in the bowel, and that beyond physical changes in the milk preparing it for bowel digestion, digestion in the stomach is of relatively little importance It was thought possible that the higher acidity of soured milk and the change in the curd might ensure a more rapid passage from the stomach and thus be of value especially where vomiting is a prominent feature It will be seen that this was not found to be the case On the other hand, as bowel digestion takes place in an alkaline medium it seems doubtful if there can be any advantage in pouring a more acid food into the bowel It is an interesting speculation as to whether such an increased acidity in the duodenal contents stimulates the pancreas, liver, and duodenal glands to increase their secretions or not So far this remains a speculation, but in the case of a feeble and marasmic infant it seems probable that any response which could be evoked would be feeble Recent work by Schiff and Gottstein[5] on the reaction of the duodenal contents after the administration of acidified milk mixtures is of interest They seem to show that acidified food does not produce any prolonged acidification of the duodenal contents Consequently it seems probable that some increase in alkaline secretions must occur Other workers in this field may also be quoted—for instance, Hahn obtained a pH of 5 0 at the height of gastric digestion, a result confirmed by Salge, and this according to Van Dam is the optimum reaction for rennin and also according to Davidsohn for gastric lipase[6] This corresponds closely with Faber's views and again shows the usual absence of free HCl at the height of digestion

Method

The stomach contents were withdrawn one hour after a feed, and the amount noted This was filtered and the pH estimated colorimetrically The HCl deficit and the total and combined acidity were estimated by titration against N/10 NaOH, using in the first case Congo red and in the second phenolphthalein as indicators. Each feed represented one-sixth of the caloric requirements of the individual infant

The infants available for study were those admitted to the observation ward of the Carnegie Institute; a large percentage were suffering from different types of infantile dyspepsia or enteritis, but normal infants were also studied, including those who were admitted with their mothers for the restoration of breast feeding, and others suffering from mismanagement The number studied could have been larger with advantage, but the results correspond very closely with those of other observers where they are comparable and may therefore be taken as accurate averages

TABLE I

Food.	pH of gastric contents withdrawn after one hour	Percentage of food left in stomach	No of cases
C M and water p a with sugar	4 8	27	13
Above with 10 15 gr p a. sod bic	5 6	24	5
Above with 20 per cent HCl	3 7	36	2
Whole C M with sugar	4 9	46	11
Acidified whole milk (culture)	4·0	56	11

Whey reconstituted from whey powder	7	117	36	153	43

Results with Different Foods

The publication of tables showing results in individual cases is contra-indicated by considerations of space and it has, therefore, seemed best to give a simple table of averages for each type of food This to some extent diminishes the contrasts In considering these results the pH of milks before feeding should be considered These averaged as follows Breast milk, pH 6 5 , cow's milk, pH 6 4 ; cow's milk with 20 per cent HCl N/10, pH 5 2 , lactic acid milk, pH 5 0 , ideal milk, pH 6 2 , dried milk (diluted 1 15), pH 6 6

It will be seen from Tables I and II that with the ordinary types of feeding—viz , milk and water mixtures (half and half), dried milk, and condensed milk (in similar dilutions), the pH concentration does not vary markedly from breast milk. The acidity is not affected by small variations in fat percentage, skim milk giving the same result as whole milk. There appears to be little difficulty in obtaining a sufficient secretion of HCl to meet the need of what may be considered a suitable pH for gastric digestion in infancy, taking the acidity in the case of a healthy breast-fed infant as a standard Secway mixtures give a low pH The reason for this is seen in the high buffer value (Table II) A low acidity is also obtained when soda bicarbonate or potassium citrate is added to the milk. In these cases the pH is below the optimum formulated by the authorities previously quoted, but this only occurs with these alkaline milks The acidified milks give a definitely higher pH.

The HCl deficiency with milks of the same dilution remains fairly constant and about double that of the breast milk Acidified whole milk gives practically the same deficit as whole sweet milk. The reason may be that the physical condition of the milk hastens digestion It will be noted that the buffer value is given plus free fatty acids ; it is obtained by adding the HCl deficit and total and combined acidity, and consequently must include free fatty acids The acid milk gives a high figure owing to a high total and combined acidity with more free fatty acid The figure for whey is in contrast with this and represents a large HCl deficit

The rate at which the stomach empties varies within fairly wide limits in individual cases, but does appear to be affected rather by the physical properties of the food than by the pH concentration Thus, where whole milk has been fed either sweet, citrated or acidified, over 45 per cent of the contents remain in the stomach after one hour, whereas with breast milk or dilutions of cow's milk under 40 per cent remains

Results in Different Conditions

Grouping the results by the condition of the child's health in certain of the cases, the average pH obtained is shown in Table III

TABLE III.

—	No of exam.	Ordinary feeds	Ac. milk.	Alk. and Secway mixtures
Healthy	19	4 9	4 3	6·0
Enteritis .	24	4 8	4 5	5 6
Dyspepsias	17	4 7	4 1	—
Bronchitis, Pyelitis, &c	8	5·0	—	5 9

It will be seen that the variation is not great but that in acute illness there is a slight fall in acidity such as might be expected

Further Considerations

As a result of careful observation of individual cases, the conclusion has been reached that the amount of gastric acidity is not of great importance In relation to vomiting the character of the curd, and the consistency of the food mixture, together with the fat percentage, appears to be of much greater importance. Where the curd is soft and flocculent, higher fat percentages appear to be better tolerated, as in acidified milk, and as in Ideal milk given as whole milk. Rennet milk apparently gives similar results In this connexion the work of Rogatz[7] on the peristolic function of the stomach should be remembered On the other hand there can be no doubt that lactic acid milk, prepared by souring with the *Bacillus bulgaricus* or similar organism, is a very valuable food in certain cases, though its value is felt to lie in its biological rather than in its chemical action The results have been very striking in some very obstinate cases of enteritis, and have been associated with a change in the intestinal flora This has been found to be the case only in a very definite group of cases —viz , infective enteritis—and lactic acid milk has not proved a universal panacea, but is undoubtedly a most valuable adjuvant A very interesting study of the results on intestinal flora by the use of milk acidified by the *Streptococcus lacticus* has just been published by Alan Brown[8] and others The results obtained are most suggestive

Lactic Acid Milk

Method of Preparation —The milk has been soured with *B bulgaricus* Repeated subcultures in the feeding-room have been avoided owing to the dangers of contamination The milk is sterilised in litre

TABLE IV.—TEN CASES OF ENTERITIS TREATED WITH LACTIC ACID MILK.

Case	Age.	Condition.	Symptoms.	Food	Stools		Result
					Before.	Later	
1. U B .	6 mths.	C E	Wasted 1½ lb loss of weight in one week D, no V	A S M and D M Later A whole milk.	—	—	Complete recovery in four weeks Sent home on ordinary milk two weeks later
2. P. P. .	8 mths.	C E	Very wasted and feeble D V.	A S M and D M	Green, alkaline, mucus and blood + + Gram + b and cocci pr	One month Similar, Gram + b now pr, less blood and mucus.	Slow imp Discharged in 3 weeks on dried milk and has done well.
3 L. H .	1 mth	C E.	Wasted, feeble, V. Stools green, slimy	,,	Green, alkaline, mucus and blood + Gram + b and cocci pr	Three months No marked change	Child imp very slowly Relapsed on going home and was sent to Babies' Hosp
4 K. R .	2½ mths	C E	Very wasted D V Severe recurrent attacks	,,	Acid reac (green) Mucus and blood + Gram + b. pr	Four months No mucus or blood Gram + b. pr Reac acid	Slow imp with repeated relapses Finally well and gaining weight
5. A. G. . .	6 wks	C E	Wasted, D, V	,,	Green, acid, mucus and blood + + Gram + b. and cocci pr	One month Pasty, yellow No mucus Acid. Cocci and Gram + b. pr.	Imp steadily on acidified milk after no imp on other food.
6 B. W .	5 mths	C E	Wasting, D V., pain.	A S M and D M After one month of other foods Later A whole milk.	Acid, green, mucus and blood + + Gram + b and Gram + b and cocci pr	One month Yellow, pasty, neutral blood present Gram b + and cocci pr	Rapid and steady imp. No relapses
7. N C.	7 mths	C E	Wasting, D. V, urticaria	A S M and D M after 14 days.	Acid, mucus and blood + Gram + b and cocci pr	Ten days Alkaline. Yellow, pasty No mucus, blood still present. Gram + b and cocci pr.	Rapid and steady imp
8. J G .	3 mths	C E	Wasting, D V.	A S M after one week	Green and loose Acid Mucus + + No blood Gram + b and cocci pr	One month Alkaline, yellow, and pasty No blood. Gram – and Gram + b, with cocci pr	Rapid and steady imp.
9 S F. .	4 mths	C E	Wasted, D V., pain	Breast milk with A whole milk	Green, slimy Acid Mucus and blood + + Gram + b and cocci pr.	Three weeks Alkaline, yellow, pasty, Tr of blood Gram + and – b and cocci pr	Rapid imp
10 L V.	12 mths	A E	Wasted and feeble, D. V.	A milk with jelly and sponge biscuits	No record.	Ten days Pale and slimy Alkaline, blood and mucus + + Gram + b and cocci pr Ten days later Loose alkaline Little blood. Gram + b and Gram – b pr	Imp steadily

C E. = Chronic enteritis, A = Acute D and V = *Diarrhœa and vomiting* A S M and D M = Acidified skim milks and dextri maltose. B = Bacilli. Pr. = Predominate. Imp = Improvement

Case 3 relapsed, but it was felt that there was here a fresh infection for the house was dirty and overcrowded and enteritis was prevalent at the time

flasks. inoculated, and then incubated for eight hours The curd is broken up with a fork and then passed through a sieve It is given in suitable dilutions or as whole milk. Skim milk is frequently used where fat curds are present in the stools in large quantities, ¼ oz. of top milk being removed in each pint When sweetened infants take this milk well There is more difficulty with older children with whom, moreover, it has not proved very useful

Method of Use —On admission it has been usual to keep the infant for a few days on the milk mixture it has been receiving at home. only modifying glaring errors in quantity or percentage composition. Subsequently ½ oz. mixtures of dried milk. or other simple mixtures have been tried before using lactic acid milk. This has made it possible to exclude those cases in which the child is suffering simply from mismanagement. or unsuitable feeding rather than from a chronic infective condition which is believed to be the one type really benefited by the lactic acid milk mixture Quite half the children suffering from loss of weight, vomiting or diarrhœa improve rapidly with the correction of their diet and hygienic conditions alone.

Details of ten cases of the type which benefits most markedly. and usually very rapidly, are given in Table IV It is not easy in a table of this kind to bring out the impression given to the clinical observer, but no one can watch these cases and fail to be impressed with the rapid change in the character of the stools, and the general improvement in the child s health. In fact unless an improvement is obtained within eight to ten days the probability is that the method will not be successful. There have been two or three instances where no improvement has resulted, the child being so wasted and feeble that it was practically moribund before treatment was begun In another type of case. where vomiting is a prominent feature. the stools improve, but the general benefit is disappointing. vomiting continues, and the child fails to gain weight. In these cases other foods, such as thickened foods. have been required subsequently. The soured milk having markedly improved the bowel conditions the child then responds more readily to such treatment. Two cases may be given :—

CASE 1—F. J 3½ months. Chronic enteritis, wasted vomiting — — Stools green and acid mucus — —. No blood. Gram — bacilli predominate. Acidified skim milk and dextri-maltose given. Stools improved quickly, became yellow pasty, alkaline, with a preponderance of Gram-negative organisms. Vomiting continued. No satisfactory gain in weight Now put on alternate feeds of lactic acid milk and thickened foods (Benger's 1 oz. to 1 pint milk) Vomiting then ceased. Satisfactory gain in weight.

CASE 2.—E H., 3 months Chronic enteritis. Vomiting — +. Diarrhœa from time to time. Wasted. Stools loose, green acid. Mucus and blood — Preponderance of Gram — bacilli and cocci Given acidified skim milk and dextri-maltose. Stools improved quickly, became pasty with no blood. Preponderance of Gram — organisms. Vomiting continued but was less frequent. Weight unsatisfactory. Given Bengers and milk feed entirely. Good gain in weight resulted. Stools remained satisfactory.

The most difficult cases for ordinary treatment are undoubtedly those of the chronic infective type. A history of early septic infection is frequent—e g. umbilical sepsis. ' pemphigus neonatorum " or other skin rashes. The infants are very wasted look toxic, and fail to improve steadily although carefully fed and tended The stools are generally greenish, slimy. and curdy They show the most marked reaction to the benzidine test for blood. The smear preparation stained by the Gram method shows a mixed flora in which usually the Gram-positive organisms, cocci and bacilli predominate If the child is benefiting by lactic acid milk-feeding the stools become pasty and smooth, only a faint reaction is given to the benzidine test and the character of the Gram film changes becoming more negative in appearance. As soon as the child appears well enough simple milk mixtures are gradually substituted for the lactic acid mixtures. No child has been sent home on soured milk. Acidified skim milk (hand-skimmed by removing ¼ oz of top milk) has been used in the severe cases before trying whole-milk mixtures Dextri-maltose has been preferred to the other sugars as apparently less irritating Quite good results have been obtained in mild cases by using skim milk and dextri-maltose without acidification. but this fails in the more severe types.

Lactic Acid Milk in Other Cases

Infantile eczema is one of the most troublesome ailments, and not less so because it usually occurs in healthy infants Ideal milk and dried milk give fairly good results and are certainly preferable to fresh milk mixtures. but even more promising results have been obtained from lactic acid milk in several cases. for example :—

Case S P., aged 8 months Weight 19 lb Covered with eczematous rash. Whole body involved. Diet. Milk, rusks, &c. Eosinophilia (8 per cent.) present. Acidified milk, rusks and bread and butter prescribed with a simple calamine lotion for the skin. In three weeks the rash disappeared, and reappeared on giving two feeds daily of ordinary milk. The child was finally sent home on a dried milk mixture with some recurrence of rash.

This method of feeding has not proved beneficial for vomiting infants with fairly normal stools; it has been tried in a number of instances quite unsuccessfully Thickened feeds, whole milk citrated, or rennet milk have given better results.

Conclusions.

1 The infant unless acutely ill, appears capable of secreting sufficient HCl to obtain a pH concentration corresponding fairly constantly to that given by breast milk on any milk mixture ordinarily used. This may be considered the normal pH required. and it appears doubtful whether, as far as gastric digestion is concerned, any benefit is obtained by using acid milk mixtures raising the pH to a higher concentration

2. No benefit has been seen in cases of chronic vomiting apart from enteritis.

3 Lactic acid milk. soured biologically, has a high curative value in chronic enteritis, whether this is due (*a*) to the replacement of pathogenic by harmless organisms: (*b*) to the greater acidity of the duodenal contents, even if existing for a brief period only, stimulating the digestive secretions. and leading to the production of a less irritant end-product with a consequent diminution of inflammatory reaction; (*c*) to both factors taking part, must remain doubtful, but the evidence appears to favour (*c*)

4. The changes produced in milk by souring appear to render it a suitable food in infantile eczema. Possibly it would prove useful in urticarias of a severe type. but the use of soured milk in the average home is fraught with danger from pathogenic contaminations

---

SUSSEX PROVIDENT SCHEME.—This scheme was affected by the industrial disturbance, but a temporary falling-off in subscriptions has been followed by remarkable recovery During the first half of the year a total of £3462 was paid to coöperating hospitals for services rendered. This includes £1880 to the Royal Sussex County Hospital.

CANCER CAMPAIGN IN MANCHESTER.—The Manchester committee proposes further investigation into the origin and prevention of mule-spinner's cancer Dr. C. C. Twort. who has been appointed pathologist to the committee, will carry out this work at the University being assisted by a chemist and other specialists The after-histories of patients treated at the Royal Infirmary and the Christie Hospital are being carefully examined. A special sub-committee has been appointed to issue information to the public on the incidence and treatment of cancer and the Manchester Insurance Committee has sent a subscription for the furtherance of its work. From Oct. 1st onwards a series of 12 lectures on various aspects of the cancer problem will be given by medical men in connexion with a post-graduate course at the Manchester Royal Infirmary and the University

INTRA-UTERINE INJECTION OF PURE GLYCERINE.

AN EXPERIMENTAL INQUIRY INTO THE BACTERIOLOGICAL BASIS FOR THE LOCAL TREATMENT OF PUERPERAL SEPSIS AND ALLIED CONDITIONS BY THIS MEANS

By ARTHUR COMPTON, D Sc, M D N U I,
SURGICAL UNIT, ST MARY'S HOSPITAL MEDICAL SCHOOL, LATE OF THE PASTEUR INSTITUTE, PARIS, EX-CHIEF OF LABORATORY, AMERICAN HOSPITAL OF PARIS

Glycerine has found many practical applications in medicine The striking work of Remington Hobbs [1] and the noteworthy clinical results obtained by him and his co-workers,[2] from the assiduous practice during the past few years of intra-uterine injections of pure glycerine for the treatment of septic conditions of the uterus and its appendages, bid fair to constitute for it an application of the most dramatic and far-reaching importance The beneficent action of the glycerine is attributed by Hobbs mainly to its physical action as a lymphagogue, setting up a drainage of the tissues which results in a washing away of offending bacteria from the surface and the deeper parts of the inflamed region

We think, however, that its action goes further than this, no account being taken in this explanation of any direct action of the glycerine on the bacteria themselves Yet a considerable independent literature exists in regard to the latter It is the author's object in the present paper to call attention to some of this work, to give at the same time an account of a few experiments carried out on the action of glycerine on certain pathogenic types of bacteria met with in the female genito-urinary tract, and to consider to a limited extent the action of glycerine on tissue cells It is hoped thereby to contribute to a more complete understanding of the action of glycerine in inflammatory phenomena, more particularly in connexion with this gynæcological problem

Action of Glycerine on Bacteria.

Nutritive Properties and Stimulating Effect on Bacterial Growth —It is well known that glycerine when incorporated in artificial culture media in proportions of about 1 per cent can be utilised by many bacteria for their own particular needs and functions How the glycerine is utilised depends in a special way upon the bacterial species Thus *yeasts*, according to Duclaux,[3] burn glycerine totally, with the transitory production of oxalic acid, which in its turn is used up by the growing yeast. Another bacterial transformation of glycerine is into dioxyacetone by oxidation, established by the work of Bertrand [4] with *B sorbose* A number of organisms studied by Castellani [5] ferment glycerine with the production of acid and gas, notably *B coli*, *B columbensis*, and *B asiaticus* Another interesting bacterial transformation of glycerine is into acrolein, by dehydration, due to an organism found in drinking-water by Voisenet[6], to which microbe he gave the name of *B amaracrylus* Again, glycerine is known to stimulate the growth of certain microbes Nocard and Roux [7] first pointed out that heavier cultures of the tubercle bacillus were obtained in broth when glycerine was present, in proportions varying between 2 and 8 per cent

Restraining Action on Bacterial Growth —In stronger concentrations in culture media the glycerine is found to act as a deterrent to bacterial growth

In order to establish the nature of this arrest of microbial development, whether antiseptic (simple inhibition of growth) or bactericidal (killing of the bacteria) experiments were performed which showed that direct contact with glycerine up to 50 per cent failed to kill *B coli*, the organism retaining its vitality for several days, although unable to multiply, or at least not doing so Further, it was found that this organism supported contact even with pure glycerine for at least two hours This indicates that the action of the glycerine is primarily an antiseptic one, and only in extreme conditions does it become disinfectant or bactericidal Bactericidal effects, as concerns *B coli*, only come into play when the organisms remain in contact with pure glycerine for a period somewhere beyond two hours, it is doubtful whether such conditions of concentration and time have ever been realised when glycerine is brought into contact with bacteria in the tissues, as in the intra-uterine injection technique

D'Herelle,[8] in a study of the organisms of dysentery and typhoid fever (*B shiga* and *B typhosus*) reports findings of a like nature He infers from his experiments that glycerine in strong doses inhibits the culture of ordinary bacteria, the inhibition being of a hindering nature rather than a bactericidal one

The time that bacteria could retain their vitality in pure glycerine was then investigated and six micro organismal types met with in the vagina were studied *B coli*, *B cutis communis*, enterococcus, gonococcus, staphylococcus, and streptococcus

Experiment —Pure cultures of these organisms were heavily inoculated into pure glycerine, and at two hourly intervals subcultures were made either on to agar slopes or into glucose broth The glycerine suspensions were well agitated after each withdrawal, that the reagent might act to fullest advantage throughout the duration of the experiment Table I sets out the results obtained

This experiment shows clearly that different organisms possess different degrees of vital resistance to prolonged contact with pure glycerine, some being more fragile than others

The principle here involved has long been utilised to practical advantage by bacteriologists, although the author is unaware of any exact study, such as the above, determining these time limits—as, for instance, in the well-known use of glycerine for the purification and preservation of certain of the ultramicroscopic viruses (vaccinia, rabies, and poliomyelitis) A recent application of the same principle is C C Twort's [9] useful method for the isolation of *B tuberculosis* from contaminating organisms in sputum

The time limits of the antiseptic and the bactericidal response of the bacteria dealt with in Table I towards pure glycerine is seen thus to be as given in Table II

These findings show how feeble is the purely bactericidal action exerted by glycerine on bacterial cells For practical application they emphasise how

TABLE I

extended is the antiseptic, and how limited the bactericidal range of its action

Of special interest is the noteworthy fact about the power of glycerine to deal with the streptococcus—the organism whose proliferation and activity in the uterus and the lacerated vagina it is above all essential to curb in puerperal infections Next to the gonococcus it is the most fragile of the organisms studied in vital resistance to contact with glycerine It is a comparatively early victim to the bactericidal effects of the glycerine, but long before that stage is reached the antiseptic powers of the glycerine are at work restraining growth This latter action is practically the only one available in the time interval available when concentrated glycerine is injected into the uterus for the reduction of inflammation To such a degree, then, it is possible to affirm that glycerine acts as an antiseptic when used as intra-uterine injections for arresting secondary hæmorrhage in the puerperium, and the clearing up of inflammatory discharges from that viscus

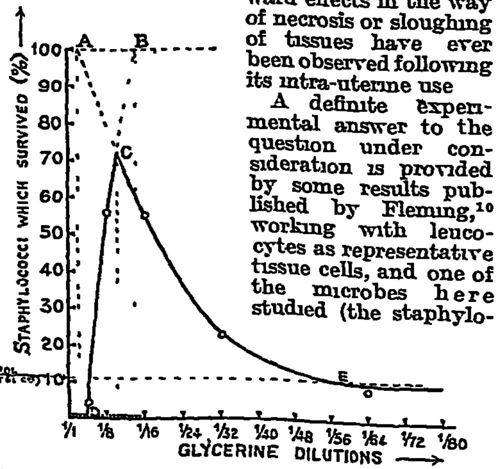
Action of Glycerine on Tissue Cells

The problem which now arises for consideration is the degree of toxicity of glycerine for tissue cells in relation to its toxicity for bacteria, whether there is a sufficient difference between these two toxicities in favour of the tissue cells to warrant the glycerine being pushed to its extreme degree as an antiseptic and bactericidal agent, as is obviously attempted when pure glycerine is injected into the uterine cavity.

The mildly irritant effects of glycerine when applied to surface epithelium—due to its abstraction of fluid from the cells—are well known But no untoward effects in the way of necrosis or sloughing of tissues have ever been observed following its intra-uterine use

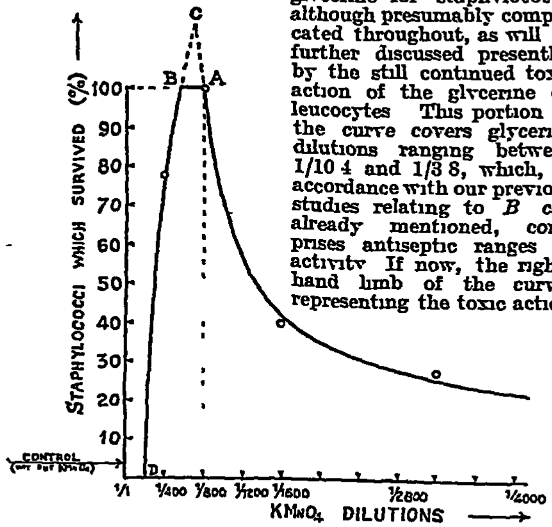
A definite experimental answer to the question under consideration is provided by some results published by Fleming,[10] working with leucocytes as representative tissue cells, and one of the microbes here studied (the staphylococcus) This author cultivated the staphylococcus in "slide cells" containing defibrinated blood and different strengths of glycerine, and after incubation at 37° C for one, two, or more days enumerated the number of colonies which developed In Fig 1 are shown the series of readings obtained by him plotted as a curve, with dilution of glycerine as abscissæ and percentage of microbes which survived as ordinates

Fig 1



This curve, when read from right to left, is seen to begin as a horizontal line corresponding to glycerine concentrations too feeble to exert any influence either upon leucocytes or bacteria (the "indifferent zone" of Fleming); it then slowly ascends towards the left, portraying the toxic effect of increasing glycerine concentrations on leucocytes, here the glycerine is primarily attacking leucocytes, interfering with their bactericidal power, and allowing the implanted staphylococci to grow out The curve next passes by a maximum,[11] in or about the glycerine dilution of 1/10 4, after which it rapidly descends This rapid descent on the left is primarily an expression of the toxicity of glycerine for staphylococci, although presumably complicated throughout, as will be further discussed presently, by the still continued toxic action of the glycerine on leucocytes This portion of the curve covers glycerine dilutions ranging between 1/10 4 and 1/3 8, which, in accordance with our previous studies relating to *B coli* already mentioned, comprises antiseptic ranges of activity If now, the right-hand limb of the curve, representing the toxic action of the glycerine on leucocytes be continued upwards to meet the 100 per cent, or total implant, line, as is indicated by the portion C A in the diagram, we obtain a point A which theoretically should represent the dilution of glycerine at which the activity of leucocytes would be so completely eliminated that all the staphylococci implanted would grow out, were it not for the antiseptic action, already begun, of the glycerine on the bacteria themselves

Fig. 2



It will be remarked in passing that the dilution at which antiseptic action begins is presumably given by the point B, obtained by prolonging upwards the left limb of the curve until it meets the total implant line; at this dilution all the bacteria implanted would grow out were it not for the bactericidal action of the leucocytes, a mechanism which as yet is far from being totally paralysed

Now, on this reasoning and interpretation of Fleming's experiment, it will be evident that the answer to the question put forward at the commencement of this section—namely, the relative toxicity of glycerine for tissue cells and for bacteria—will be given by a consideration of the position of the point A in relation to the point D, where the curve of action meets the zero line At D no staphylococci can survive; at A no leucocytes, or the bactericidal power of the blood which they represent, can survive The point A is found thus by interpolation to correspond to a glycerine dilution of approximately 1/2 4 (or a glycerine concentration of 41 7 per cent), the point D to a dilution of approximately 1/3 8 (or a glycerine concentration of 26 3 per cent) This means, then, that the leucocytes, as typical tissue cells, when pushed to it, can support a much higher concentration of glycerine (actually approximately 15 per cent more) than can staphylococci; and bacteriologically these latter are usually considered to be a fairly resistant type of micro-organism This conclusion is reached in spite of the fact that the attack on leucocytes by glycerine begins earlier, at the point marked E on the diagram, than does the attack on staphylococci, at the point B

---

[10] Proc Roy Soc., 1924, B 96, 171–180

[11] This maximum on the curve of activity, it will be evident, is not a true maximum in the mathematical sense of being a balance point between two opposing forces It would appear, as indicated, to be simply the point of intersection of two curved lines, and if it is to be defined at all it might be called the *maximum freedom from restraint point of the bacteria* under the conditions of the experiment

Thus it is seen that it is the end-points A and D which ultimately count in judging the value of an antiseptic by this particular experimental method, the author is of opinion that this is an aspect of the question which has hitherto not received adequate attention Finally, let us consider briefly, for the sake of comparison, the story which potassium permanganate yields when interpreted graphically in like fashion

Fig 2 gives the curve for $KMnO_4$ which follows from the experimental data furnished by Fleming The curve in this case rises to the 100 per cent line, so that the point A, instead of being imaginary as in the case of glycerine (Fig 1), is real Next the curve appears to pass through a flat region, A B—covering $KMnO_4$ dilutions which would allow all the staphylococci implanted to grow out—to fall from B to the zero at D

This zone (A B), which it remains for future investigation to confirm experimentally, is a new type of "indifferent zone," and to distinguish it from that described by Fleming it might be called a *bacterial indifferent zone*, the indifferent zone of that author being a *leucocytic indifferent zone*[12]

Here, also, the point B is real, although there is some little difficulty in fixing it exactly from the data available, no observations having been recorded for antiseptic dilutions lower than 1/400 Still, in view of the reading recorded for 1/400 there is good reason to suppose that the representation of the left limb of the curve is approximately that portrayed In any case, and this is the important feature of the curve, it shows that the attack on leucocytes is over and finished with (the point A) long before even the antiseptic action has been begun (the point B), and still longer before the antiseptic action can be complete (the point D)

This establishes the fact that potassium permanganate possesses a markedly greater paralysing effect on the tissue cells of blood than on a typically resistant microbe, like the staphylococcus As an antiseptic, then, it is certain to do more harm than good, unless the organism to be combated is one much more fragile than the staphylococcus And this analysis of the activity of potassium permanganate merely serves to bring out in greater relief the vast superiority of glycerine for antiseptic and surgical use, when dealing with an organism like the staphylococcus

General Conclusion and Summary

That the bacteriological basis for the treatment of puerperal sepsis and allied conditions by the intra-uterine use of glycerine, as conceived by Hobbs, is well founded is borne out by an analysis of the behaviour of tissue cells and bacteria to this reagent

In a study of the former—from data published by Fleming, based on an ingenious application of the "slide cell" technique of Wright—we have been able to show that glycerine is an ideal antiseptic in the sense of being less fundamentally toxic for leucocytes, as representative tissue cells, than for typically resistant bacteria like the staphylococcus Incidentally, in this connexion, we have indicated how it is possible by the use of a graphic method of presentation of slide cell results to define more completely the theoretical terms of an antiseptic As examples of two fundamentally different types of cyto-bacterial activity curves, those for glycerine and potassium permanganate are figured

A new antiseptic characteristic is indicated, the *bacterial indifferent zone of cyto-bacterial activity*, which —being present in the case of antiseptics possessing greater toxicity for tissue cells than for bacteria, and absent in the case of antiseptics possessing greater toxicity for bacteria than for tissue cells—affords a criterion for the selection of useful antiseptics and the rejection of those likely to do more harm than good.

In a study of the direct action of glycerine on various bacterial types met with in the genito-urinary tract it is established that pure glycerine is but feebly bactericidal in comparison with its markedly antiseptic character The time limits of its bactericidal and of its antiseptic responses to a number of bacteria are indicated The streptococcus is seen to succumb comparatively early to the bactericidal action of glycerine

The new facts brought to light make glycerine one of the most interesting and ideal antiseptics, and indicate for it a sphere of even greater usefulness in the treatment of inflammatory conditions

---

[12] These zones distinguish themselves from each other in that for dilutions of the antiseptic corresponding to the "bacterial indifferent zone" the bacteria are indifferent to the presence of the antiseptic as concerns toxic effects, while, in the "leucocytic indifferent zone," it is the leucocytes which show indifference to the presence of the antiseptic Again, in the matter of bacterial growth, in the "leucocytic indifferent zone" the leucocytes are able to inhibit bacterial growth to the extent of the control without glycerine, while in the "bacterial indifferent zone" the bactericidal function of leucocytes being lost, they are powerless to restrain growth, and the bacteria all grow out, until the antiseptic dilution is reached at which toxicity for bacteria comes into play

---

THE
ACTION OF LIGHT ON COD-LIVER OIL.

By P R PEACOCK, M B, B S Lond,
VAUGHAN MORGAN SCHOLAR AND MARGARET BUTCHER SCHOLAR, MIDDLESEX HOSPITAL.

In January, 1925, during the examination of many oils and fats under ultra-violet illumination, it was noticed that cod-liver oil was very brightly fluorescent The sample of oil stood, in a 100 c cm round glass flask plugged with cotton-wool, on the laboratory bench, untouched from January to June of last year, when I again had occasion to examine the fluorescence of the oil The second examination showed that the oil had completely lost its fluorescence, though by ordinary light it appeared unchanged

The following explanations of this phenomenon seemed to be possible (1) That the oil had reacted with atmospheric gases leading to oxidation (2) That the effect was due to variations in temperature (3) That the effect was due to absorption by the oil of heat, light, or ultra-violet radiations

Confirmatory Experiments

June 3rd, 1925 Two samples of very brightly fluorescent cod-liver oil were sealed in soft glass tubing of 6 mm. bore and 1 mm wall thickness One tube was covered with rubber tubing to exclude light and ultra-violet rays, and both tubes were then set side by side in the sun's rays Daily examination revealed complete loss of fluorescence in the uncovered sample on the fifth day The control was still brightly fluorescent

June 12th Four tubes similar to those used in previous experiment were half filled with fluorescent cod-liver oil. Two were sealed in air, two in vacuo (Sprengel pump) One tube containing air and one vacuum tube were covered with thin black paper to exclude light and the four tubes were then set on the hospital roof for irradiation Both uncovered tubes had lost their fluorescence after approximately ten hours' sunshine, the controls remaining unaffected

The above experiments suggested that the effect was not a simple oxidation due to contact with the air or to the presence of dissolved oxygen in the oil The conditions as regards temperature were the same for the controls, so that this factor is eliminated We are left with the possibility of the effect being due to light or "near" ultra-violet rays (up to 3100 A U.), the "far" ultra-violet being excluded by the glass

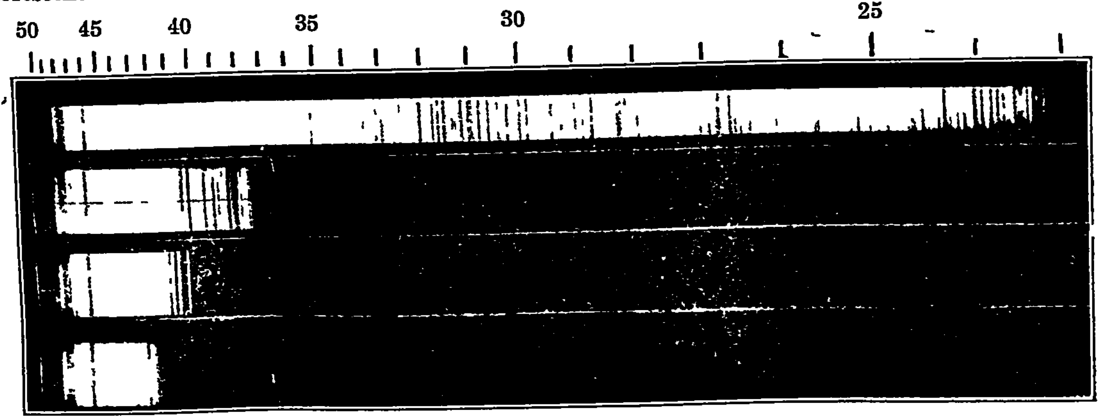
During the last year this phenomenon of the destruction of fluorescence in cod-liver oil by exposure to light has been repeated so often and under such varying conditions that it is probably a constant effect. For the sake of brevity, the term "delumination" was coined to signify the loss of fluorescence described above In addition to sunlight, "delumination" has been produced by the tungsten-cored carbon arc, the mercury-vapour lamp, and a fullolite gas-filled lamp The times required range from ten hours in brilliant summer sunshine to five days under the metal filament lamp at a distance of 5 cm

It appears that a certain critical intensity of light is required to upset the equilibrium of the oil and initiate the process of "delumination," for, in the winter, the effect is not observed in samples of oil which have been exposed for several months to daylight Deluminated oil, stored for many months in the dark, recovers some of its fluorescence, but, within the period of these experiments, none has regained its original brilliance

Vitamin Content

One of the first questions that suggests itself is "Has the phenomenon of delumination any relation to the vitamin content of the oil ?"

Vitamin A. The presence of this vitamin is easily tested, thanks to the work of Dr O Rosenheim and Prof J C Drummond,[1] whose colour reaction for vitamin A corresponds accurately with the results of animal tests The addition of ½ c cm of arsenic chloride to a drop of cod-liver oil in a small tube gives, in the presence of vitamin A, a blue colour which fades in a few minutes on standing Samples of fluorescent and of deluminated oil were tested by this means, normal cod-liver oil gave the reaction strongly, deluminated oil gave a completely negative reaction The effect has been repeatedly demonstrated and can be regarded as constant for deluminated oil



I Emission spectrum of condensed iron spark
II Absorption spectrum of deluminated cod-liver oil
III Absorption spectrum of cod-liver oil in which the vitamin A has been destroyed by sunlight.
IV Absorption spectrum of normal cod liver oil

It was necessary to investigate in detail the relationship between the delumination of cod-liver oil and the destruction of its vitamin-A content, and a description of the methods employed to solve this problem may be given at this point

The oil used was a well-known proprietary brand of Newfoundland cod-liver oil, which is very constant as regards specific gravity, colour, odour, fluorescence, absorption spectrum, and vitamin-A reaction, and is tested biologically for fat soluble vitamins before being supplied to the public This oil is supplied in brown glass bottles, which incidentally protect it from the effects of light

The oil to be examined was first drawn into soft glass tubing of 7 mm bore and 0 5 mm wall thickness, which was then sealed The tube of oil was then placed vertically in front of the slit of a quartz spectrograph (A. Hilger, size C) and the absorption spectrum of the oil was photographed The source of light used was a condensed iron spark giving a very uniform distribution of closely packed lines extending far into the ultra-violet region The absorption of the glass may be neglected as it is less than that of the contained oil (see figure) The tube was then unsealed and the oil, after being re-tested for vitamin A and found to be strongly positive, was drawn into fine capillary glass tubes of 1 to 2 mm bore and less than ½ mm. wall thickness These tubes were sealed and set in a row in the sunlight

Frequent tests were made for vitamin A until the reaction was faintly positive, when each tube was tested repeatedly until a negative reaction was obtained, the tube being then put in the dark to prevent further delumination of the oil Sufficient oil was thus obtained for absorption spectra to be taken under the same conditions as for normal cod-liver oil, as described above

Comparison of the absorption spectra shows at once that the destruction of vitamin A corresponds with an increase in the transmission spectrum, the limit for normal cod-liver oil being 4100 A U, that for the oil in which vitamin A has just been destroyed being 3900 A U Both samples of oil are still fluorescent, but the irradiated sample is definitely less brilliant than the control sample of normal oil

From these experiments it is evident that "delumination" and destruction of vitamin A, though parallel, are not identical phenomena, as further delumination can be obtained after destruction of vitamin A is complete In further support of this view is the fact that fully deluminated oil after nearly a year in darkness recovers much of its fluorescence but still fails to give the colour test for vitamin A This latter observation shows that we are dealing with a complex reaction which is apparently partly reversible

At a meeting of the Physiological Society held at Cambridge on June 5th a demonstration of the action of light on cod-liver oil was given by the writer, in collaboration with Dr S Wright,[2] when the results of preliminary animal experiments were put before the meeting

Rats fed on a basal diet deficient in vitamin A were protected from xerophthalmia and continued to put on weight when 2 per cent normal cod-liver oil was added to the diet

Similar animals on the same basal diet, to which 2 per cent deluminated oil was added in place of the normal oil, developed marked xerophthalmia and began to lose weight

Substitution of normal for deluminated oil in the diet caused a rapid recovery in these animals

These results are in complete accord with the foregoing experiments and appear to confirm the destruction of vitamin A in cod-liver oil by exposure to sunlight

Vitamin D By the courtesy of Prof C J Martin, of the Lister Institute, I was able to examine under the ultra-violet rays samples of cod-liver oil of known degrees of antirachitic potency There seemed to be no association between the fluorescence and the antirachitic value of the various oils and extracts Samples of inactive cotton-seed oil showed no difference from similar oil which had been rendered actively antirachitic by exposure to ultra-violet rays It was thought from these observations that there was no evidence to suggest destruction of the antirachitic vitamin in cod-liver oil by sunlight

Summary

Exposure of normal cod-liver oil to any source of white light of sufficient intensity results in the following changes (1) The normal bright golden fluorescence of the oil progressively disappears, this effect being termed "delumination" (2) Before full "delumination" occurs the oil fails to give the arsenic chloride test for vitamin A (3) Fully "deluminated" oil, when kept for some months in the dark, slowly regains much of its fluorescence, but the vitamin A appears to be permanently destroyed (4) There is a change in the absorption spectrum corresponding with change in the fluorescence of the oil As "delumination" proceeds, so the transmission spectrum extends into the ultra-violet region, as fluorescence returns there is a proportionate return of the absorption spectrum

[1] O Rosenheim and J C Drummond Biochemical Journal, 1925, vol xix, No 5

[2] P R Peacock and S Wright Proceedings of the Physiological Society, June 5th, 1926, p 36

This paper has a double object, first, to emphasise the fact that light is a variable factor which must be taken into account in all quantitative experiments concerning the growth-promoting properties of cod-liver oil and the manner in which such oil is stored, secondly, to call attention to the unusual nature of the complex reaction of cod-liver oil to light, a reaction which is only partly reversible

Clinical and Laboratory Notes.

TONIC SPASM OF THE EYES IN CONJUGATE DEVIATION

By Mary R Barkas, M D Lond, D P M.,
ASSISTANT MEDICAL OFFICER, MAUDSLEY HOSPITAL

The emotional instability of some cases showing disorders of the basal ganglia has led frequently to their being regarded as hysterical, and this view has very naturally been taken of the symptom I am about to describe This is the spasmodic conjugate deviation of the eyes upwards, usually to one side, accompanied by subjective distress and acute depressions

Three Cases

The first case in which this symptom was noticed was one of progressive lenticular degeneration, the patient had been recommended for admission as hysterical, but when seen was recognised to be suffering from an organic disease of the Parkinson type She was childish and emotional, subject to spasmodic laughing and crying, and began to complain that her "eyes got fixed,' this being associated with great distress At first this occurred rarely and lasted for only a few moments, but it has become more frequent and the attacks will last for any time up to about an hour She can always move the eyes voluntarily, but this requires an effort, and they return when the effort is relaxed to the fixed position of conjugate deviation upwards and to the left There is no nystagmus at any time in this patient and she has never had diplopia Visual fields are normal

The second case was sent from an infirmary, where she had been taken on account of threats of suicide, as she was depressed about the 'fixing' of her eyes and thought this made her conspicuous This had been her first symptom, beginning about a year ago, and she had noticed that emotional stress, such as anxiety about her husband, brought on the attacks In these her eyes move up and to the left, become fixed, can be brought down by volitional effort, but soon return to the position of spasm There is nystagmus on looking to the right, and she has had diplopia when reading, possibly due to refractive error and neglect to wear her glasses Visual fields are normal Later she developed spasmodic torticollis, independent of the eye symptom, and weakness and tremor of the right arm of the Parkinson type She denies having ever seen anyone previously with similar symptoms

The third case was a young man who complained that his eyes turned up and became fixed on Mondays he was a bank clerk Further investigation showed ankle-clonus on one side, and a history of encephalitis lethargica was elicited, with transient diplopia The eye symptom was associated with depression.

Comment

Since seeing these cases reference to the literature has discovered a paper by Marinesco and Radovici[1] in which the conjugate deviation of the head and eyes in paroxysmal hypertonic attacks is described in three cases of post-encephalitic Parkinsonism, they suggest that these are due to some factor in the basal ganglia which is either not functioning normally or is not controlled normally by the cortex In our cases the deviation of the eyes occurs alone, the head remaining in the flexed Parkinson posture in one case, while in the other a spasmodic torticollis occurs, but at separate times and under different circumstances from the eye symptom Since the symptom is of a kind likely to be disregarded or considered hysterical, it seems worth while to draw attention to it as being, in some cases at least, an early manifestation of a serious and progressive organic disease Its constant association with spasmodic attacks of depression or weeping affords further evidence of the close relation between the basal ganglia and the emotions, and tempts one to speculate as to a possible organic basis through which the emotions may produce physical manifestations in hysteria

I wish to thank Dr E Mapother, the medical superintendent of the Maudsley Hospital, for his permission to refer to these cases, who have been in-patients of the hospital He also informs me that he has met with a similar case in his practice where the same eye symptoms were associated with choreiform movements in a post-encephalitic case

NOTES ON AN OUTBREAK OF INFANTILE DIARRHŒA ASSOCIATED WITH A PARASITIC FUNGUS

By H A Cookson, M B, Ch B, F R C S Edin, D P H Camb
PATHOLOGIST, ROYAL INFIRMARY, SUNDERLAND, BACTERIOLOGIST, SUNDERLAND HEALTH AUTHORITY,
AND
E Thorp, O B E, L R C S Edin, D P H Belf,
TEMPORARY MEDICAL OFFICER OF HEALTH, HEALTH DEPARTMENT, SUNDERLAND

For the past two years we have been meeting with many cases of diarrhœa in young children, which have caused an abnormal death-rate from that disease The symptoms are the usual ones of many stools—blood being frequently present, quick loss of weight, and vomiting Two types appeared to exist—a very acute type and a four-week type From time to time one of us (H A C) examined the stools and sera of cases for members of the enteric, dysentery, and other groups of organisms associated with the incidence of diarrhœa among young children It was next observed that children who suffered from stomatitis appeared also at a later period to suffer from diarrhœa As the diarrhœa remained prevalent and the death-rate unduly high it was definitely decided to attack the disease more systematically

One of us (E T) was concerned with the clinical and hygienic aspects of the investigation and stools were obtained from acutely ill children for bacteriological examinations, and in one instance also serum from a convalescent was fully investigated It had been noted that if the children were removed to hospital on the first or second day, and inter alia careful attention given to the toilet of the mouth speedy recovery took place The bacteriological examination, a summary of which is appended, would appear to incriminate *Oïdium albicans* as the causal organism, for whereas it appears in debilitated adults as a more or less harmless parasite, in children it without doubt produces diarrhœa Acting on this possibility lectures were instituted to be given by the health visitors on cleanliness of the mouth and the rigid treatment of all lesions due to thrush and the look-out to be kept for such conditions This has effected a remarkable improvement in the returns, it would therefore appear very advisable in all cases of diarrhœa amongst young children to examine with care the mouth for thrush or ulcerative stomatitis and to treat if necessary

Ten stools were examined microscopically and bacteriologically, of these seven showed mycelium and spores of *Oïdium albicans*, no member of the enteric or dysentery group was found, and the stools had no other micro-organismal factor in common other than the oïdium The serum of a convalescent patient was tried for agglutinins against a large range of members of the typhoid-colon group No such agglutinins were demonstrated

BRITISH MEDICAL ASSOCIATION

ANNUAL MEETING AT NOTTINGHAM

(Continued from p 289)

SECTION OF ANÆSTHETICS

WEDNESDAY, JULY 21ST

THE first session of this Section was opened by the President, Dr SAMUEL JOHNSTON (Toronto), who reviewed the benefits of anæsthesia and discussed its future It was essential, he said, that anæsthetists should be well grounded in basic sciences such as physics, chemistry, and pharmacology, and, where practicable, technique should be learnt on animals The ideal ought to be that every qualified man should be able to give a safe, efficient, and pleasant anæsthesia in cases of labour and minor surgery A certain number of more highly qualified anæsthetists should be available for the hospital work of the smaller towns and these should hold positions comparable to those of staff anæsthetists in the teaching hospitals The three groups of anæsthetists all had their special functions, but on the last named particularly devolved the onus of developing the art Some idea of the progress achieved in 25 years could be gained by considering the growth of the anæsthesia department of the Toronto General Hospital, which now consisted of a chief and eight assistants, all of them specialists It was not too much to hope that in the near future a chair of anæsthesia would be established in every university where medicine is taught There was no doubt that the routine use of the uniform anæsthesia record charts issued by the International Anæsthesia Research Society would prevent a large number of fatalities These charts require the following essentials (1) evaluation of risk and determination of pre-operative treatment, (2) five-minute blood-pressure records to enable anti-shock treatment to be instituted promptly, and (3) determination of post-operative treatment The Society was at present concentrating on the production of a more elaborate teaching anæsthetic chart

Development in anæsthesia was proceeding apace, as was evident from reports of new general and local anæsthetics A uniform standard of purity was very desirable, and a committee of investigation had already been formed by the British Medical Research Council and the Anæsthetic Section of the Royal Society of Medicine New inventions must be made public in strict accordance with medical ethics, and the royalties accruing should be devoted to further research In all these efforts the patient's point of view must remain paramount, and anæsthetists would do well to appropriate the motto of the Pacific Coast Association, " It is God-like to relieve pain," and that of the Canadian Society, " We safeguard those who sleep "

Dr WESLEY BOURNE (Montreal) read a paper on the Effect of Some Impurities in Ether on Respiration and Blood Pressure He showed lantern slides which demonstrated that acetaldehyde, ether peroxide, and ethyl sulphide all caused a lowered blood pressure and respiratory embarrassment in a dilution of 1 per cent in ether Ethyl mercaptan in an infinitesimal proportion caused a most nauseating odour, but all the ketones tried—acetone, dimethyl ketone, and methyl ethyl ketone—appeared to exert no deleterious influence even up to a concentration of 5 per cent

Dr R E APPERLY (London) said that in spite of Dr Bourne's investigations, he thought that the minute traces of aldehydes in ether had a prejudicial effect upon recovery.

Dr H M COHEN (Manchester) read a paper on journals dealing with anæsthesia, from the publication of Morton's Circular in 1847 down to the present day, and emphasised their value to practitioners and to research

Dr C W. MOOTS (Toledo, Ohio) read a paper on Coöperation with the Surgeons, in which he dealt first with the importance of post-graduate teaching in anæsthetics It was very desirable, he said, that surgeons should understand the theory of anæsthesia so as to be able to coöperate with anæsthetists by the use of a technique minimising shock and enabling the smallest possible dose of anæsthetic to be employed. He emphasised the importance of keeping blood-pressure charts, and said that in his opinion the best index of a patient's condition was the pressure ratio —i e , the fraction: $\frac{\text{pulse pressure}}{\text{diastolic pressure}}$ This should remain between 70 and 30 per cent , otherwise the operative risk was extremely bad

Dr F H MCMECHAN (Ohio) laid stress on the necessity for preventing needless deaths not only on the operating table, but also during the 72 hours that followed operation

The second session was opened by Dr MCMECHAN with a paper on

The Newer Gaseous Anæsthetics

It had been remarked, he said, that an ideal anæsthetic gas should be one which has a sufficient solubility in water to be carried to the central nervous system, which has so high a solubility in lipoids as to lead to its differential accumulation there, and which will leave the body rapidly and unchanged Nitrous oxide had been used for years as an anæsthetic, but its great drawback was that practically the whole of the nitrogen in the body must be displaced. This was attempted clinically by secondary saturation. Recent work on theories of anæsthesia had disclosed electrical changes in anæsthetised animals but these were of theoretical rather than practical importance The metabolic concept of anæsthesia, however, was of great interest, as it supposed that diminished oxidation in lipoid tissue occurs, and that it can be brought about either by oxygen restriction or by partial saturation with lipoid-soluble anæsthetics, such as chloroform and ether These two factors in their turn involved changes in the acid-base equilibrium. It was the duty of an anæsthetist to render these changes as negligible as possible When using any gas anæsthetic it was absolutely essential that it should be perfectly pure The most minute trace of other substances might lead to considerable danger. The relative potency and toxicity of gas anæsthetics might be expressed as follows, ethylene being taken as unity Nitrous oxide, 0 85, ethylene, 1; acetylene, 1 5, propylene, 2 25, butylene, 4 5; amylene, 15 The oxygen-content for an anæsthetic mixture also rose in the same order, being about 10 per cent in the case of nitrous oxide, 12–15 per cent for ethylene, and 30 per cent for acetylene. With propylene, an inert gas such as nitrogen could be used to dilute the mixture and render it non-inflammable, but this mixture was liable to cause circulatory collapse some hours after administration The methane series of gases did not show much promise as anæsthetics The rapid saturation of the body and equally rapid elimination of the gas anæsthetics constituted their chief advantage It had been shown that if gas anæsthetics could be given with oxygen in a pressure chamber under one-sixth of an added atmosphere, the resulting anæsthesia would not only be better but safer than at atmospheric pressure It had also been demonstrated that the gas anæsthetics did not enter into any combination with hæmoglobin, and had less effect upon the hydrogen-ion concentration of the blood and upon carbohydrate metabolism than have ether, chloroform, and ethyl chloride They had less effect on renal function Some observers believed that the gas anæsthetics increased oozing from raw surfaces but it was doubtful whether this action was perceptible On the other hand, they did increase, rather than decrease, uterine contractions, thus behaving in the opposite way to chloroform and ether The blood pressure was maintained far longer than with the older anæsthetics, while their action on the myocardium appeared to be negligible.

Dr. E I McKesson (Toledo) elaborated Dr. McMechan's paper by pointing out the differences in anæsthetic signs between nitrous oxide-oxygen and ethylene-oxygen, drawing the conclusion that ethylene was more depressing and powerful generally than nitrous oxide

Dr J D Goldman pointed out that with nitrous oxide oxygen deficiency was inevitable, with ethylene it could sometimes be avoided, but with acetylene the oxygen content of arterial blood could always be kept within normal limits It was essential, however, that all traces of acetone should be removed from the gas

Dr S R Wilson pointed out that deep hypnosis, trance, and hibernation presented similar phenomena to anæsthesia, and suggested that it might be of value to study these conditions more closely

Thursday, July 22nd

At the third session Dr F W Price (London) opened a discussion on

Anæsthesia in Relation to Cardiovascular Affections

He began by remarking that an opinion on the risk of administering an anæsthetic to a subject with some cardiovascular affection was usually given with some difficulty Speaking generally, it was surprising how well patients with cardiovascular affections took anæsthetics, the exceptions being usually those with chronic myocardial disease The fundamental question was whether the impaired heart and other parts of the cardiovascular system were capable of withstanding the added strain of an operation and anæsthetic In the majority of cases only palpation and auscultation were required to arrive at a decision, sometimes the use of a sphygmograph was helpful, but only occasionally was it necessary to employ a clinical polygraph or the electrocardiograph The rate and rhythm of the heart should always be determined at the cardiac apex because the rate of the radial pulse did not necessarily represent the ventricular rate, and in order to determine the type of irregularity It was often difficult to decide whether tachycardia and bradycardia were physiological or pathological An increase of more than 15 beats per minute when the patient assumed an upright posture was suggestive of vasomotor instability The increase in rate from physical exertion varied greatly, but help might be gained from the presence or absence of accompanying subjective symptoms of cardiac distress The possibilities of atony of the heart muscle from lack of physical exercise and poisoning without structural damage must also be borne in mind The time elapsing before the cardiac rate returned to normal after physical exertion was of greater significance than the degree of increase induced by the exertion Dr Price then described the characteristics of various forms of irregularity of the heart's action, and discussed their significance in prognosis Attention, he said, should be directed to examining the walls of arteries other than the radial before excluding disease, and the size of the heart should be carefully estimated To decide on the importance of a murmur, the patient should always be examined standing up and lying down, before and after gentle exercise, and during the various phases of respiration It should be remembered that a valvular defect was a mechanical impediment to the heart muscle in its work and that there were usually coincident changes in the myocardium, aorta, and coronary arteries In valvular lesions due to previous acute endocarditis, the prognosis was better than when primary chronic endocarditis or syphilis was the cause Sudden death was most likely to occur in fatty and fibroid degeneration of the myocardium, in angina pectoris, in aortic incompetence, and in the sudden closure of the lumen of a coronary artery It was of the greatest importance to ascertain whether a lesion had affected the myocardium, and a guide to this was the heart's response to effort—in other words, the amount of physical exertion which did not cause symptoms of cardiac distress It was of value to inquire whether the patient's normal standard had decreased and, if so, to what extent (Temporary causes such as anæmia and mental strain must be excluded) The usual symptoms of distress were breathlessness, palpitation, fatigue, and precordial pain The last of these might not occur for some hours The pain of angina pectoris was felt most commonly in the retrosternal region, and there might be cerebral symptoms, including giddiness, fainting attacks, and seizures resembling petit mal, and the Adams-Stokes's syndrome Fatalities had occurred during anæsthesia owing to inadequate treatment of the heart condition beforehand—the condition could often be vastly improved by giving digitalis by mouth, or, in urgent cases, by the intravenous injection of strophanthin In choosing an anæsthetic it was important to remember that the symptoms of cardiac failure in mitral disease were mainly respiratory, whilst the symptoms in aortic disease and in fatty degeneration of the myocardium are those of systemic anæmia, here the chief danger was of syncope and anything that lowered the blood pressure should be avoided In arterial disease, aneurysm, and angina pectoris, on the other hand, the blood pressure should not be raised Chloroform should be avoided in heart-block, and intermittent and very light anæsthesia was always undesirable

Dr J Blomfield said that it was remarkable how few fatalities occurred during anæsthesia in patients with cardiac lesions There was hardly any cardiac disease so advanced that it would not permit some form of anæsthesia or analgesia to be employed for an emergency operation In severe cases it was essential that the patient should retain the position for easiest breathing, and there should be no asphyxia Anæsthetics causing least muscular spasm should be employed, an unobstructed airway should be maintained, and oxygen should be given continuously A useful rough test was the length of time a patient could hold a deep inspiration If this was under 30 seconds it would probably be dangerous to give a general anæsthetic Myocardial degeneration without valvular lesions was the bugbear of anæsthetists, and in doubtful cases a cardiologist should be consulted

Dr E. von der Porten said that in his opinion patients with cardiovascular lesions should be kept lightly anæsthetised and a preliminary injection of morphia and atropine should be given

Dr A L Flemming (Bristol) emphasised the importance of a quiet and unhurried induction period.

Dr Mary Botsford (California) said that a consideration of the patient's previous history was important She thought that psychic shock should be avoided and that nitrous oxide-oxygen anæsthesia with preliminary morphia and atropine medication was indicated

Lady Berry (London) laid stress upon the desirability of preliminary rest and administration of digitalis Morphia she considered unsatisfactory, and she usually employed atropine alone, followed by light ether anæsthesia Patients should be talked to as they were going under

Dr Crighton Bramwell (Manchester) said that except in aortic disease, Stokes-Adams's syndrome, and fatty or fibroid degeneration of the myocardium, syncope was generally due to vasomotor instability Bradycardia apart from heart-block was favourable, but pulsus alternans without tachycardia was always of grave import

Dr H W Featherstone (Birmingham) said that extrasystoles frequently disappeared under anæsthesia He disliked using chloroform and spinal anæsthesia as he found that the systolic blood pressure tended to fall more than the diastolic

Dr H P Fairlie (Glasgow) said that it was in the post-operative stage that collapse frequently occurred in cardiac cases

At the fourth session Dr E I McKesson gave a lecture on

Some Physical Factors in the Administration of Gaseous Anæsthetics.

The anæsthetist, he said, altered the gaseous content of the tissues to effect a reduction of oxidation or metabolism in certain nervous tissue without similarly affecting the metabolism of other tissues This was the result of a combination of factors: (1) The solubility of gases in the body fluids (2) The difference in oxygen requirements of the different tissues It had been shown that nervous tissue requires a more liberal supply of oxygen than do other tissues Consequently, at certain tensions of N_2O and O_2 in the body fluids the activity of certain nerve-cells was curtailed while other more stable nerve-cells and those of muscle and other tissues would find sufficient oxygen to carry on their normal functions (3) An absence of chemical change of the anæsthetic gas while in the body. An apparatus for administering gaseous anæsthetics, said Dr McKesson, must exclude air, it must embody a positive control of the gases administered; it must control the pressure of the mixed gases and regulate rebreathing, and it must provide a means of inflating the lungs with oxygen. He showed how his own apparatus fulfilled these conditions

Dr Goldman and Dr Thompson Rowling (Leeds) also gave demonstrations of apparatus, and Dr. S R Wilson gave a lantern lecture on the Evolution of Anæsthesia

A joint discussion on July 23rd with the Section of Surgery on Anæsthesia in Abdominal Surgery has already been reported in The Lancet (August 7th, p 285).

SECTION OF PATHOLOGY AND BACTERIOLOGY.

Thursday, July 22nd

At the first meeting of this Section Prof Sholto Douglas (Sheffield), the President, paid a tribute to the late Sir William Leishman, who was to have presided over the Section and through whose efforts the programme was arranged Those present stood in silence for a moment in honour of the memory of this eminent pathologist

Dr R A O'Brien (Beckenham) opened a discussion on

The Relationship of Streptococci to Scarlet Fever and its Complications

He summarised the grounds for a belief in the existence of such a relationship as being (1) the invariable presence of these organisms in the throat in scarlet fever; (2) the production (by the Drs Dick) of clinical scarlet fever by the introduction of cultures of the organisms into the throats of susceptible individuals; (3) the production of a toxin by the streptococci in question which of itself will produce many symptoms of the disease; (4) the ability of an antitoxic serum produced against this toxin, to abolish the rash of scarlet fever. and (5) the good therapeutic results obtained by treatment of the disease with such serum Proceeding to analyse these data, Dr O'Brien discussed the characters by which the *Streptococcus scarlatinæ* might be identified The question had been found to present the usual difficulties of streptococcus classification Culturally there were no features distinguishing such strains from the *Streptococcus pyogenes* and the most satisfactory method of recognition was by means of the agglutination test which in the hands of experienced workers engaged upon this special variety of research gave fairly reliable results Here, however as in other branches of streptococcus work there was overlapping and the identification of individual cultures was difficult · the streptococci closely related to the scarlatinal group were those of erysipelas Another question awaiting answer was the significance of the various subgroups which serological methods revealed within the main scarlatinal group Did such division correspond to different clinical types of scarlet fever or were all such groups identical in the results produced? The available evidence pointed to the latter suggestion being correct and Dr O'Brien believed that the various subtypes of scarlatinal streptococcus produced one and the same toxin as do the various agglutination types of *B diphtheriæ* The most convincing evidence of the relationship of a given streptococcus to the disease was its power of producing a toxin which gave the specific intradermal reaction (Dick test) and which was neutralised by a scarlet fever antitoxin. Similarly, if an antitoxin made from the toxin of such a streptococcus produced specific blanching of the scarlet fever rash (Schultz-Charlton phenomenon) there was good evidence for assuming a causal connexion of that organism with the disease. An interesting side issue was the determination of the true nature of so-called puerperal scarlet fever, surgical scarlet fever, and allied conditions not of an infectious nature: this problem might be solved by the study of these reactions There remained the question of the mode of action of the organism Is it toxigenic or is its action direct as it is in ordinary septic processes? Dr O'Brien considered that anti-scarlatinal serum, if given early in the disease, gave sufficiently striking results to make it comparable to diphtheria antitoxin, in consequence he believed that scarlet fever, in this stage at all events, was a toxic process

Dr C C Okell (Beckenham) dealt mainly with the technical aspects of agglutination and toxin study in connexion with the streptococci found in scarlet fever The view that these organisms were causal was a satisfactory working hypothesis, but discrepancies were numerous One of the major difficulties in working upon the condition was the lack of any reliable test for the standardisation of toxin and antitoxin At the present time the only practical method was by means of the Dick test, which meant working with human subjects, and here the reaction, although definite and specific, was not quantitative He thought it desirable to carry out standardisation by reference to a known serum rather than to a toxin; such a serum was being prepared in America for the purpose. At the present time toxin neutralisation tests only gave a very rough estimate of the therapeutic efficiency of a serum The Ramon test had been tried for standardisation but had not been found of any value. Laboratory animals were not susceptible to the toxin although readily killed by the living organisms against which an antitoxic serum might or might not protect them Dr Okell's experience of the agglutination test for the identification of the scarlatinal streptococcus agreed in general with the published statements.

Dr K. E Birkhaug (New York) said that in examining 500 cases of scarlet fever in New York he had found the scarlet fever streptococcus in 96 per cent during the first four days of the illness. The organisms had disappeared from the tonsillar crypts by about the tenth day of the disease, at which time the patients' blood contained enough antibodies to yield the Schultz-Charlton phenomenon He had found identical streptococci in non-scarlatinal conditions such as osteomyelitis and tonsillitis Agglutination was an unsatisfactory method of identification on account of the frequency of spontaneous flocculation, the best criterion being the human skin test He had examined the Schultz-Charlton phenomenon by Krogh's method of direct examination of the capillaries and had found that these were dilated to about three times their normal size whilst the rash was present and showed progressive constriction when the blanching serum was injected He agreed with other speakers as to the efficacy of serum treatment.

The President urged the necessity for establishing an adequate pathological service in connexion with the isolation hospitals of this country. Usually the pathological work was left to persons quite unfitted to do it and an enormous amount of valuable material was not investigated

Prof W J. TULLOCH (St Andrews) compared the subgroups of the *Streptococcus scarlatinæ* group with those of tetanus Agglutination differences did not mean differences in the variety of toxin produced He suggested that the delicacy of the Ramon test for antitoxin estimation depended upon the ions in play and that by studying this factor a usuable modification might be devised

Dr PAGE SUTHERLAND (Manchester) spoke of the routine use of the Schick and Dick tests at Monsall Hospital valuable information as to the chance of cross infection was obtained and the latter test was found useful in confirming the diagnosis The susceptibility of members of the nursing staff was tested as a routine and prophylactic immunisation of susceptible persons was an important economic measure

Dr BIRKHAUG read a paper on

The Streptococci of Erysipelas

He said that by means of agglutination and absorption tests he had demonstrated that 91 per cent of hæmolytic streptococci isolated from cases of erysipelas fell into a definite group which was serologically distinct from the scarlet fever group and also from streptococci isolated from common septic conditions A serum prepared from the erysipelas strains protected rabbits against infection with similar strains but did not confer immunity against streptococci from other sources The intracutaneous injection of these erysipelas organisms into normal rabbits produced a condition strikingly resembling human erysipelas, and with a toxin obtained from the organisms a skin reaction akin to the Dick reaction could be demonstrated Dr Birkhaug further reported results of the use of an antiserum prepared from the erysipelas streptococci and used in human erysipelas The clinical trial of such a serum in 60 patients suggested that it had striking therapeutic effects when administered early in the disease and in adequate dosage The average dose given was 100 c cm of the unconcentrated serum and in most cases a single dose sufficed The injection was usually followed by a critical drop in temperature, an amelioration of the general condition, and the disappearance of the eruption In late cases the chief effect of the serum was in the amelioration of the toxic condition, its local results being less striking

FRIDAY, JULY 23RD

Prof G L GULLAND (Edinburgh) opened a discussion on

Leukæmia and Allied Conditions

and reviewed various theories of its nature. From the supposition that the disease was a suppuration of the blood, Prof Gulland dealt with supposed parasites which in their turn had become discredited At the present day the view was held in some quarters that it was an infective condition, and certainly cases of acute leukæmia clinically simulated the infections The leukæmia of fowls was a virus disease and human leukæmia might correspond to it The sum of all the available evidence, he thought, pointed to the disease being neoplastic, its special features being due to the fact that the white cells of the blood are not normally cohesive and permeate all tissues and fluids without themselves forming a tissue in the proper sense In leukæmia true tumour masses occurred in the bone-marrow and in certain organs, and the cells overflowed into the blood giving the well-known blood pictures Prof Gulland divided leukæmias into granular and non-granular classes, recognising in the latter lymphatic and myeloblastic types He considered that the cells met with in both classes were derived from a common marrow cell, the myeloblast or lymphoidocyte normally present in the bone-marrow but only active in pathological conditions Normally, the cells of the non-granular series were derived from a large lymphocyte and those of the granular series developed through an intermediate cell or promyelocyte The leukæmic process might affect any of these cells at any stage of their normal life-history, but when the granular forms were involved in a chronic type of the disease all the varieties of leucocytes participated in the proliferative process The reason for the simultaneous involvement of the non-granular cells was hard to find Both the acute granular and the chronic non-granular forms were rare, the latter being perhaps the most interesting type of leukæmia and often extremely chronic, the glandular enlargement might exist for ten years before the true diagnosis was made In such cases there was often remarkably little interference with the patient's health until the final breakdown occurred The existence of an acute lymphatic form of the disease was open to doubt, many cases described as such were the terminal phase of a chronic lymphatic leukæmia and showed very high white cell counts which would indicate a condition of long duration Others were in reality examples of myeloblastic leukæmia, and it must be remembered that in all such cases a coincident excess of true lymphocytes was the rule In the early stage of such cases the total white count might be only a little increased, but a certain proportion of myeloblasts would be present, which proportion would be found to increase as the disease progressed In leukæmic patients death was not due to the excess of white cells, but was a result of accompanying anæmia, hæmorrhage, or intercurrent conditions The causation of the associated anæmia was interesting In Prof Gulland's opinion it was to be found in the rate at which the leucoblastic transformation of the marrow took place If it advanced slowly, as in the chronic forms of the disease, time was left for compensatory activity on the part of the red-cell producing marrow, but if the process was rapid, or if the leukæmic transformation in chronic cases transgressed a certain limit, the physical possibilities of reaction by the erythroblastic tissue were so reduced as to result in a severe grade of anæmia As a consequence of irradiation the overgrowth of white cells might be checked and a chance of recovery offered to the red-cell-producing marrow to which it often responded very successfully With regard to allied conditions, chloroma was a true leukæmia and presented no real difficulties in diagnosis Whooping-cough and glandular fever sometimes occasioned difficulties; both showed a lymphocytosis and in the latter there was enlargement of the glands and spleen The greatest difficulty was in the aleukæmic stage of leukæmias, especially where anæmia was a prominent feature, here the diagnosis between leukæmia and pernicious anæmia was often in doubt and ultimate resolution of the difficulty by the pathologist was a result which the speaker strove to avoid

Dr S W PATTERSON (Ruthin) reviewed a series of cases of disease of the blood-forming organs classified as tumours of glands, tumours of spleen, and tumours of the mediastinum In the first group he included acute leukæmia (11 cases), glandular fever, and Hodgkin's disease He remarked that in Australia the combination of tubercle with Hodgkin's disease was not seen in the way it occurs in this country Under tumours of the spleen he included myeloid leukæmia, and the various types of splenic anæmia and acholuric jaundice The cases of mediastinal tumour included nine examples of Hodgkin's disease, seven of lymphosarcoma, and four of fibrosarcoma He expressed the view that the treatment of leukæmia by irradiation was equally destructive to both red and white blood elements

The PRESIDENT spoke of the difficulty of differentiating the non-granular types and asked what was the value of the oxidase reaction He put forward the suggestion that leukæmia was sometimes seen in epidemic form

Dr R DONALDSON (London) said that text-book classifications of leukæmia were too rigid He opposed the view that leukæmia was a sarcomatosis If this were so, then blood-forming tissue in malignancy behaved differently to other tissues, as instanced by its universal involvement True neoplasms of the bone-marrow were rare He preferred the view that the disease was due to a virus or an irritant; the clinical manifestations were more in accord with such a causation than with tumour growth, and its long duration was opposed to a neoplastic origin There was an obvious fault in the regulating mechanism of leucocyte numbers whose mode of function was unknown As far as he had been able to ascertain there was no increase in the incidence of the disease The records of St George's Hospital for the last ten years showed the admission of nine cases of acute lymphatic disease, seven of the chronic variety, and ten cases of myeloid leukæmia

Prof GULLAND, replying, denied that X rays or other leucocyte-destroying agencies produced anæmia, nothing was more definite than the improvement in the anæmic condition which took place as a result of such therapeutic measures The oxidase reaction often failed where it was most wanted, only certain myeloblasts gave it and the reaction probably depended on the cells' age He thought that there was no evidence of an epidemic tendency in leukæmia. With regard to the sarcoma view of the disease, he allowed that it was only provisional, but it was the view which best fitted the accepted facts. The remissions of the disease were quite unexplained, it was possible to produce them by benzol, but he considered that this drug only acted on the circulatory leucocytes, when its administration was stopped they returned with a bound and there was no evidence of its having any effect on the marrow

Dr T S P STRANGEWAYS (Cambridge) read a short paper in connexion with his demonstration with Dr CANTI on

Tissue Culture

Dark-ground illumination, he said, was better than any other method for studying the structure of the living cell. Man was to be looked upon as a cell colony produced by the repeated division of a single cell, and in his constitution two main types of cell were to be distinguished—the somatic and the germ cells The somatic cells surrounded the germ cells and formed tissues and organs which are built up for the purposes of the germ cell The somatic cells possessed the power of multiplication and of reproduction of their own type, but the germ cells were potentially immortal The death of an animal did not cause the simultaneous death of the body cells, which survived for a long time and might be obtained in cultures made some days after the death of the animal. Cells might easily be cultivated in plasma and certain tissue extracts outside the body and showed in their cytoplasm fat granules, mitochondria, and other structures In division the cell became round and the nucleus disappeared, to reappear in the form of chromosomes in the later stages of mitosis Growing cells were mobile and might migrate from place to place This doubtless also occurred in the body and its extent and possibilities were often underestimated, the extension of tumours was probably largely caused by the mobility of the cells and, further, the repair of surgical wounds was mainly due to their migration In the formation of an innocent tumour the phenomena seen were multiplication of cells followed by their differentiation and succeeded by a stage of inhibition of further growth, in a malignant tumour the process resolved itself into the multiplication of cells plus some degree of differentiation, but no phase of inhibition followed The factors here at work were of the greatest interest in connexion with the whole problem of such growths, in ordinary cultures the multiplication of the cells would go on indefinitely if favourable conditions were provided for their growth

Dr R G CANTI (London) supplemented Dr Strangeways's remarks by giving a description of the technique of tissue culture and the detailed process of cell division which he said, lasted about five minutes He also described some interesting attempts at microdissection of the living cell

Reviews and Notices of Books.

PATHOLOGY OF THE MOUTH

By FREDERICK MOOREHEAD, M S, D D S, M D, and KAETHE W. DEWEY, M D London and Philadelphia W. B Saunders Company Pp 540 32*s* 6*d*

THERE is much truth in the statement made in the preface to this book, that the mouth taken as a whole is a neglected territory, falling between dentistry and medicine The pathological conditions which occur in the mouth may be intimately connected with the teeth and associated structures or quite unrelated to these organs, and a wide knowledge of general medicine as well as of dental disease is essential if these conditions are to be differentiated There was undoubtedly room for a book devoted entirely to the pathology of the mouth, and it is the more disappointing that the volume before us is very unequal in merit Curiously enough the strictly dental part of the book is the least satisfactory.

Three pages only are devoted to dental caries, no illustrations of the morbid anatomy being included. The opening chapter on anomalies of the teeth and jaws is so brief and uninformative that, as it stands, it is useless and might with advantage be omitted The chapter on harelip and cleft palate is disappointing. Harelip is described as the commonest defect, but although it may occur unaccompanied, in the majority of cases a harelip is associated with a complete maxillary cleft The chapter on pyorrhœa on the other hand, is good and embodies a fairly complete account of the pathology of this condition so far as it is understood In the account of diseases of the dental pulp there is no mention of the condition sometimes described as " pink spot," in which there is absorption of the tooth from within, without any external lesion In discussing hypoplasia of the teeth the authors state that the defective formation of enamel is counterbalanced by overdevelopment of the interglobular spaces in the dentine This is surely a misreading of the condition. The excessive formation of interglobular spaces in dentine is itself a hypoplasia and is precisely analogous to the defects in the enamel The authors are wrong in stating that the enamel of the deciduous teeth is completed at birth So far from this being the case not more than about two-thirds of the crowns of the incisors is formed and proportionately less in the molars and canines

The account of the various oral manifestations of syphilis, leprosy, actinomycosis, and tuberculosis are excellent and well illustrated The diseases of the tongue are fully described, though the addition of illustrations to this chapter would greatly have increased its value The account of the tumours of the mouth is on the whole excellent Especially good is the section on the fibrous and myeloid epulis The authors discuss fully the pathology of the myeloid epulis and are evidently conversant with the extensive literature on giant-celled tumours The description of the cytology and morbid anatomy of these interesting tumours is admirably done The description of the odontomata is not so good, Bland-Sutton's classification is given but the authors do not follow it There is no mention of the valuable classification introduced by Gabell, James, and Payne, though it is by now well known and appreciated by oncologists

There is a long bibliography appended to the book which adds much to its value, though not many British references are included Where illustrations are inserted they are for the most part original and admirably reproduced The book will undoubtedly prove useful to students and practitioners, while if in a future edition the weaker sections are brought up to the standard of the rest, the authors will do a service to medicine and dentistry

OTOLOGY.

Contributions to the Art and Science of Otology Lectures and Papers by RICHARD LAKE, F.R C S, 1892–1925 London: Macmillan and Co 1926 Pp 255 15*s*

THIS collection of original addresses and papers covers a large number of matters within the domain of otology, and ranges from short notes, mostly on points of real interest, to detailed articles on considered subjects Of especial interest are a series of papers on vestibulotomy in non-suppurative disease of the ear for the relief of vertigo In one of these papers, which, with many others, originally appeared in THE LANCET, he reported in 1911 10 cases in which he had performed this operation with, apparently, considerable success Several of the papers are in French, having first been published in the *Archives Internationales de Laryngologie* We notice an odd misprint in the title of one of the papers translated into French, " Factem dans la Genève de Maladies du Nez et des Oreilles," " Factem " being obviously Factum, and " Genève " Genese Taken as a whole, this collection shows an observer with a keen mind and an ardent worker, the results of whose large practical experience are worth study by practitioners as well as by specialist workers The papers record first-hand experience

IMMUNITY IN TUBERCULOSIS

The Principles of Immunity in Tuberculosis By W CAMAC WILKINSON, M D, late Lecturer in Pathology and in Medicine at the University of Sydney. London Nisbet and Co. 1926 Pp 141 10*s* 6*d*

THIS book, as we learn from the preface, was written to prepare the way for the reopening of a tuberculin dispensary in 1926 In the first chapter, which deals with the modern conception of tuberculosis, Dr Wilkinson supports the current view that much of the infection in civilised communities takes place during childhood, and later he quotes German statistics of the war period to show that soldiers who bore the stigmata of tuberculosis or who had a personal or family history of the disease, resisted a subsequent attack better than those who had no such history or stigmata In conformity with the modern German view he regards the biological history of the disease as closely analogous to that of syphilis Thus he speaks of a primary sore or lesion, a secondary stage when " the tubercle bacilli, like the treponema, spread along the lymphatics that drain the site of infection," and a stage of tertiary manifestations which usually takes the form of chronic phthisis The bovine bacillus he regards as being of relatively little importance, and in an italicised passage he states that if bovine tuberculosis were eradicated from cattle in Great Britain it would not seriously diminish the death-rate from tuberculosis in human beings

In a chapter on chronic phthisis, Dr Wilkinson lays down 11 main facts of the pathological picture of the disease, with which other experts would largely agree; but when he reaches the question of early diagnosis he diverges from the views generally held After pointing out that "occult, larval, latent tuberculosis cannot be determined . by the most meticulous search for physical signs that do not exist or cannot be seen or heard at the surface of the body," he goes on to state that " by the touchstone that can explore the deep, distant, hidden, mysterious activities of cell life, we can touch and awaken signs and symptoms as latent and quiescent as the disease itself "—that is to say, by the diagnostic use of tuberculin Setting aside a very short chapter on the nature of immunity in tuberculosis, in which the author strongly favours the cellular rather than the humoral hypothesis, the rest of the book is devoted to an exposition of the tuberculin dispensary, its methods, and its value Here he is dogmatic and at times manifestly on the defensive against critics whom he holds to be both ignorant and unreasonable In reply to the criticism that the tuberculin dispensary may be a dangerous place he retorts " The essential difference between my methods and my critic's is that I can detect the other cases [i e, those which are not acute] without fail at an early stage and restore them to health My critic cannot because he is too timid to use the only means of demonstrating this difference "

No detailed instructions are given in the book as to the methods of dosage employed, and no mention is made of the problems of standardisation of tuberculin which are exercising the minds of immunologists at the present time The author apparently regards these matters to be outside the scope of the present work, which is frankly the advocacy of the tuberculin dispensary in the treatment of tuberculosis To this extent the title of the book is misleading

THE EVOLUTION OF ORTHOPÆDIC SURGERY

By ROBERT BAYLEY OSGOOD, A B, M D, John B and Buckminster Brown Professor of Orthopædic Surgery in Harvard University St Louis C V. Mosley. 1925 With 49 illustrations Pp 70

ON the flyleaf of this brochure we are told that the terms of the gift of the Detroit Orthopædic Lectureship Fund, established Nov 24th, 1922, provide for the publication of the lecture, and for the free distribution of the same to such societies, libraries, and individuals as shall be selected by the Lectureship Foundation Committee (of the Wayne County Medical Society) as most appropriate In accordance with these terms we have been presented with this historical survey of orthopædic surgery Our professional brothers in the United States are setting a good example in the interest that they are evidently taking in the history of our art Dr Garrison's works on this subject are well known and only a few weeks ago appeared the handsome book on pediatrics of the past by Dr Ruhrah, of Baltimore The report of the lecture now under notice is a valuable if less ambitious effort in the same direction Its author acknowledges inspiration to some extent from the " Menders of the Maimed," by Keith

Dr Osgood wisely declines any attempt to define orthopædic surgery, which, however, as he points out, did not really originate before 1800 After a short sketch of the medical art from the mythical Podalirius and Machaon to Francis Glisson, and a brief excursion into the history of the physiology of periosteum and growing bone, and a short notice of John Hunter and Sir (sic) Percival Pott, we come to the early orthopædic surgeon Delpech, who has received much unmerited credit for a share in the invention of subcutaneous tenotomy but whose book, " L'Orthomorphie," was the first really important contribution to the literature of the subject, seeing that Audry's Orthopædia contained little that was surgical Dr Osgood has enriched his pages with portraits and biographical notes of some of the leaders in surgery and its ancillary sciences who are not generally considered to have been orthopædic surgeons, but on the plea that they contributed to our knowledge of the framework of the human body their inclusion may perhaps be justified, but if Paget and Brodie are to be claimed as orthopædic surgeons, where is the line to be drawn ? The numerous reproductions in this little book of portraits of distinguished physicians, surgeons, and physiologists are not worthy of the high reputation of American book-illustration, they are for the most part disappointing

THE LAW RELATING TO INJURIES TO WORKMEN

Third edition By FREDK G NEAVE, LL D, Solicitor London Effingham Wilson 1926 Pp 160 2*s*

THIS new and revised edition of one of the series known as Wilson's Legal Handy Books deals concisely with injuries to workmen under the common law, under the Employers' Liability Act, and under the

Workmen's Compensation Acts, 1906–1924, as well as with the cases decided under these statutes. It is a judiciously compressed legal statement showing the workman's choice of remedies under the not very logical system of alternatives which Parliament will perhaps one day coördinate and simplify In a book so recently published it is unfortunate that the author was unable to include references to the consolidating Workmen's Compensation Act of last year. This Act, it will be remembered, came into operation on May 1st of 1926 and, with a few minor exceptions, replaces the previous Workmen's Compensation Acts ranging from 1906 to 1924 The author's general statement of the law, and (so far as it goes) of its historical development, remains unaffected by the omission, but his references to what are now repealed statutes are misleading Text-book writers deserve all sympathy when Parliament thus upsets their publications, but it was known last year that the process of consolidation was impending and it would have been better to delay this book till the effect could be stated

---

A HISTORY OF THE LONDON HOSPITAL.

Third edition By E W MORRIS, House Governor of the Hospital London: Edward Arnold and Co 1926 Pp 303 *7s 6d*

THE third edition of this excellent history, which first appeared in 1910 has been brought up to date, and gives information as to the various changes which have occurred during the intervening period. Many new departments have been organised, new buildings to house those departments have been erected and the staff also has suffered changes A notable date was the year 1921, when Lord Knutsford completed his twenty-fifth year of service as chairman of the hospital How much the hospital owes to Lord Knutsford's energy, tact and humour as a successful beggar for the charity over which he presides cannot be put down on paper The tabular chronology of the hospital at the end of the book is interesting as showing that the duty of almsgiving is still widely recognised amongst all classes; the sums received vary from small amounts and more and varying substantial donations to an anonymous gift of £50,000 for endowment for medical research to the new sun baths given by patients who had received Finsen light treatment The account of the treatment and accommodation at the hospital in its early days may well make the modern patient thankful that he did not live in those times, and there is a grim description, p. 57 et seq, of the course of a case of compound fracture in pre-Listerian days: "The patient did well for ten days, at the end of which he complained of his bowels and of a shivering, and that upon opening some abscesses, which were found gathering in his leg, the discharge was so great that he lost his appetite and sank under it. . . Mr Harrison had ordered him fish, chicken, or anything else he could eat, and large nosegays to prevent his being affected by the stench of his leg, and that the man was thankful and particularly so on the day of his death." Many a sufferer must have welcomed death as a release from a surgical ward in those days.

Mr Morris's book is worthy of the great institution of which he is so faithful and efficient a servant.

JOURNALS

JOURNAL OF PHYSIOLOGY. Vol. LXI, No 3 June, 1926 Pp 305–464 Cambridge University Press — Lady Briscoe reports investigations on Conduction of Respiratory Nervous Impulses through Regions of Block Produced by Pressure These investigations she has summarised in THE LANCET (July 10th, p 56) —Prof J Mellanby contributes an account of the Experiments on the Secretion of Pancreatic Juice referred to in his paper in THE LANCET (July 31st, p 215) —The other papers are as follows The Conduction of a Nervous Impulse in a Narcotised Region of a Nerve, by Sybil Cooper. Until challenged recently by Kato in Japan and Forbes in America (1924) it has been taken as an established fact that when subjected to narcosis or other depressing influence a nerve conducts with a decrement—i e. that the actual change observed is reduction of the ability of conduction through narcotised nerve. Experiments with frogs' nerves, narcotised with alcohol and chloral hydrate indicated that there is conduction with a decrement and no lengthening of the recovery. The author's results on the whole do not confirm the work of Kato, but they are in agreement with the work of Lucas and others.—The Blood Count and Body Temperature in Normal Rats, by Arthur Dighton Stammers The normal red cell count in rats is in the region of 8,700,000 per c mm. at sea-level At an altitude of 6000 feet (Johannesburg) there was an increase of under 6 per cent. as compared with the 20 per cent increase seen in normal human blood at this altitude The range of body temperature of the rats in the writer's colony was 96·8°–102·2° F. Under normal circumstances, and seemingly the same conditions, the temperature of the rat apparently varies within 2° or 3°.—On Cellular Activity and Cellular Structure as Studied in the Thyroid Gland, by W. Cramer and R. J Ludford. The thyroid was chosen for an attempt to establish a correlation between changes in functional activity and in the structure of the cytoplasm as indicated by alterations in the mitochondria and the Golgi apparatus—both of which structures can be seen in living cells, and are, therefore, not artefacts Conditions were established which induce intense activity and complete inactivity respectively of these glands. Exposure to cold and the injection of β-tetrahydronaphthylamin produce an intense activity of the gland, while a resting condition is induced by exposure to a hot environment and by thyroid feeding A very clear relationship could be demonstrated between the functional state of the gland and the mitochondria In the resting gland the mitochondria are barely visible. In the active gland they show an enormous enlargement. The condition of the mitochondria, therefore presents a criterion for the functional state of the gland, and may, as Goetsch has suggested, be useful in the study of pathological states of the gland The Golgi apparatus shows the same changes which have been observed in the other gland cells in rest and activity—a simple contracted form in the resting cell an enlarged convoluted form during activity, followed by a disintegration into granules Several illustrations show the appearance of sections of the gland of the mouse at room temperature, the immediate effect of cold following heat, and the immediate effect of heat following cold, the differences being most striking. A pictographic summary of sections of the gland under various conditions of activity is given, and the significance of the mitochondral changes from the point of view of cell mechanics is discussed. The mitochondria represent a mechanism by which the cell can produce great variations of surface energy within the cytoplasm On the basis of accepted views such variations must be accompanied by changes in the distribution of the lipoids within the cytoplasm and the cell membrane These changes in turn, would affect the permeability of the cell.—The Venous Pressure of the Eye and its Relation to the Intra-ocular Pressure, by W. Stewart Duke-Elder. The author describes the methods he adopted to measure the pressures in the intra-scleral veins in dogs, that in the extra-scleral veins the intra-ocular veins, and the variations of venous pressure with intra-ocular pressure —The Spleen and the Resistance of Red Cells, by D Orahovats R. M. Pearce has shown that the resistance of the red cells of the blood from the general circulation to hypotonic salt solutions is greatly increased after splenectomy. The resistance of the red cells of the spleen pulp was compared with the resistance of the red cells of the body (1) to *hypotonic salt solutions*, (2) to saponin solutions. It was found that the red cells contained in the spleen pulp are less resistant to hypotonic solutions than the red cells from the general circulation, and the former are more resistant to saponin solutions than the latter The statement of R. M. Pearce regarding splenectomy is confirmed —On the Output of Hæmoglobin and Blood by the Spleen, by E. W. H Cruickshank A method is described for estimating in cats the blood and hæmoglobin output of the spleen without exposure of the organ. It is shown that the capacity of acting as a reservoir for blood and of concentrating hæmoglobin is a peculiar property of the spleen not shared by other muscular organs—e g , the tongue —The other papers are The Osmotic Pressure of the Proteins of Human Serum and Plasma, by E B Verney; The Relation of Work and Heat in Tortoise Muscle, by Jeffries Wyman, jun , The Influence of Length on the Responses of Unstriated Muscle, by F R Winton, and Determination of the Hydrogen-ion Concentration of the Blood, by L E Bayliss, P T Kerridge, and Ruth Conway Verney —A paper by H H Knaus, on the Action of Pituitary Extract on the Pregnant Uterus, is reviewed on p 343

MEDICINE AND THE LAW.

Inquest Quashed Duty to View Body

AT a Lancashire inquest held last March the jury found that the deceased, a boy of 16, committed suicide by shooting Application was recently made to the Divisional Court for a rule *nisi* for a writ of *certiorari* directing another inquest to be held because the coroner had not viewed the body The rule has, after argument, been made absolute, a fresh inquest has been ordered, or rather it has been decided that the inquest without view was no inquest at all and that, therefore, an inquest must be held which may be held before the same coroner The coroner made an affidavit explaining that, owing to difficulties of transport, he arrived late at the inquest, he was told by the police officer that the jury had already viewed the body and were waiting for him In these circumstances, being a solicitor with no more medical knowledge than the jury, he considered (wrongly, as he now admits) that no useful purpose would be served by his viewing the body, especially as he had had a medical report before he had ordered the inquest But, though a solicitor, he forgot that Section 4 of the Coroners Act of 1887 says that "the coroner and jury shall, at the first sitting of the inquest, view the body" This omission was fatal to the validity of the inquest It was argued on behalf of the coroner that, by the passing of the 1887 Act, Parliament outlined (in Sections 4 and 5) certain routine proceedings, and authorised the High Court (by Section 6) to dispense with a further inquest at its discretion if any irregularity had occurred. The Lord Chief Justice, following the leading case of R. *v* Ferrand decided in 1819, rejected the argument and held it to be a condition precedent that there should be a view of the body. On an application for costs, the coroner, Mr. D M. Haslewood, was ordered to pay a sum not exceeding £10 towards the applicant's costs

It may be remembered that the Government's Bill dealing with the law of coroners proposes to amend Section 4 of the 1887 Act The Bill says: "At or before the first sitting of an inquest on a body the coroner shall view the body, and, if before the body has been buried, the coroner so directs or a majority of the jury so desires, the body shall be viewed by the jury also" View by the jury (which has been noted by observers as often a perfunctory performance where the jurors are persons of refinement) is scarcely necessary except where there are wounds or injuries which raise the question of self-infliction or otherwise The recent Lancashire case was of this nature The boy had a Mauser pistol, apparently taken with him for the purpose of shooting rabbits His body was found in a lane one morning, having apparently been in that position since midnight The pistol was lying near him There was a lacerated wound in the left temple and a punctured wound in the right Medical evidence indicated that the bullet entered on the left side The boy was left-handed and in his left hand was found a partly-smoked cigarette His relatives felt that a verdict of suicide was less probable than one of accident or murder, hence, their application to quash the inquisition In face of the coroner's statement and the fact that the jury had viewed the body, it does not seem that the coroner's omission to view made any difference to the verdict The view by the coroner, however, whether under the law as it was before 1887 or under the law since 1887, or under the law as it will be if the Coroners (Amendment) Bill passes, is an indispensable formality An inquest must be, in the old phrase, *super visum corporis* No view, no inquest

Professional Discipline Cases Appeal to High Court from Quasi-Judicial Bodies

It is notorious that from time to time there has been strong criticism of the decisions of the disciplinary tribunal to which Parliament has entrusted the task of dealing with "infamous conduct in a professional respect" It has been pointed out that in other professions than that of medicine there is the safeguard of a right of appeal to the High Court from the sentence of the professional tribunal Such a right of appeal is conceded, for example, to the solicitor whose conduct has brought him before the disciplinary committee of the Law Society It was observed in this column some weeks ago that an appellant must not expect too much of this privilege of appeal to the law courts. The Lord Chief Justice, presiding over the Divisional Court, which was hearing one of these appeals under the Solicitors Acts, said that the legislature had made the Law Society master in its own house, and added that, unless the Society had gone wrong upon some question of principle or law, the matter was one for the Society's discretion and the Court would be very reluctant to interfere This particular appeal has lately found its way to a higher court, where the Master of the Rolls has emphasised afresh the discretionary powers of the Law Society "It is impossible," he said, "for any Court to lay down the exact principles upon which the Law Society must base its decisions, the legislature has entrusted it with the duty of estimating the standard of conduct to which a solicitor must attain in order properly to carry out his duties, no one could be more competent, more wise, or perhaps more merciful in judging these cases than the Law Society" One can hardly doubt that the law courts would display the same reluctance to interfere with the decisions of the professional tribunal if Parliament were moved to grant, by way of safeguard, a right of appeal to the High Court in cases under the Medical Act

The professional discipline tribunals of lawyers and of doctors have been described as quasi-judicial, if they act judicially, the law courts will be slow to interfere with their decisions On the other hand, if they fail to give natural justice, interference will be speedy enough This principle is illustrated by the recent case of Captain Peter Wright against the Bath Club A club committee, acting without bias and in accordance with the club rules, can expel a member (if the rules so provide) after first notifying him of the charges made against him and after giving him an opportunity of answering those charges A club committee is a quasi-judicial body, it is necessarily invested with a discretion to act in what it deems the best interests of the club. Captain Wright won his action against the Bath Club because the committee had strangely failed to acquaint him with the charges against him and to give him a hearing This was a denial of natural justice, the quasi-judicial body had failed to act in a judicial manner, and so the law courts intervened If one could imagine the committee of the General Medical Council similarly lapsing from judicial standards and condemning a doctor unheard, the law courts could, and doubtless would, intervene even in the present condition of the law.

are carried on Their claims are logical, since enforcement of all sanitation in each district would thus be unified Presumably the Government departments concerned have come to agreement but medical officers of health, as representative of local authorities, may yet object that their view-point has not been fully considered Possibly the balance for efficiency leans towards the procedure embodied in the Bill But whatever be the final issue, the present system of dual control is unsatisfactory.

The second matter of particular interest to doctors concerns the medical examination of young persons proposing to enter on factory life of any sort This work is laid down to be performed by "appointed doctors," and no allusion is to be found anywhere to the existing office of certifying factory surgeon, except where it is stated that under the Workmen's Compensation Act, 1925, references to a certifying surgeon shall be construed as references to an "appointed doctor" The provisions governing the examinations have been recast and strengthened, while local education authorities are called upon to produce to an "appointed doctor" the school medical record of young persons, and this officer is defined to mean a medical practitioner duly appointed to act, the appointment resting usually in the hands of the Secretary of State or chief inspector As he is to be appointed for individual factories rather than for whole districts, the assumption is reasonable that some choice of doctor may now be accorded to each establishment His fees and duties may be determined by the Secretary of State, but contracts for service are not ruled out, nor is extension of duties beyond the examination of young persons—indeed the possibility of such extension seems adumbrated elsewhere in the Bill when power is taken to arrange by order for special medical supervision of workers, where the amount of sickness or some other reason renders it desirable Somewhat unaccountably no power is given to an appointed doctor to inspect the work upon which a young person is to be employed; the omission ought to be rectified before the Bill becomes law Taken as a whole, while much must depend upon the way in which the scheme of appointed doctors is administered it seems to give opportunity for the development of an adequate factory medical service such as industry, in its own economic interests, to day badly needs In one direction, however, an interesting, but not very promising innovation is allowed for by permitting the transference of the appointment and duties of an appointed doctor to a county council Should use ever be made of this proposal, a factory would lose any say in the personality of its appointed doctor, while any extension of duties for supervising the health of adults would carry the whole-time public health staff into a realm at present unexplored by it and might end in the creation of another blind alley service, in addition to those of tuberculosis officer and school medical officer
is may be due to some interdepartmental com-
mise, but the factory medical service will have a chance if it be free from dual control

MEDICINE AND THE LAW.

Inquest Quashed Duty to View Body.

AT a Lancashire inquest held last March the jury found that the deceased, a boy of 16, committed suicide by shooting Application was recently made to the Divisional Court for a rule *nisi* for a writ of *certiorari* directing another inquest to be held because the coroner had not viewed the body The rule has, after argument, been made absolute, a fresh inquest has been ordered, or rather it has been decided that the inquest without view was no inquest at all and that, therefore, an inquest must be held which may be held before the same coroner The coroner made an affidavit explaining that, owing to difficulties of transport, he arrived late at the inquest, he was told by the police officer that the jury had already viewed the body and were waiting for him In these circumstances, being a solicitor with no more medical knowledge than the jury, he considered (wrongly, as he now admits) that no useful purpose would be served by his viewing the body, especially as he had had a medical report before he had ordered the inquest But, though a solicitor, he forgot that Section 4 of the Coroners Act of 1887 says that "the coroner and jury shall, at the first sitting of the inquest, view the body" This omission was fatal to the validity of the inquest. It was argued on behalf of the coroner that, by the passing of the 1887 Act, Parliament outlined (in Sections 4 and 5) certain routine proceedings, and authorised the High Court (by Section 6) to dispense with a further inquest at its discretion if any irregularity had occurred The Lord Chief Justice, following the leading case of R. v Ferrand decided in 1819, rejected the argument and held it to be a condition precedent that there should be a view of the body. On an application for costs, the coroner, Mr. D M Haslewood, was ordered to pay a sum not exceeding £10 towards the applicant's costs

It may be remembered that the Government's

THE FACTORY BILL

A quarter of a century has elapsed since the last Consolidating Act of 1901, and during the period not only have considerable alterations and additions been made to our code of factory legislation, but great changes have taken place in the outlook on such legislation. A Bill, distinctly overdue if only on account of the need to simplify the procedure of enforcement, has now, however, been introduced to consolidate enactments at present scattered in 13 different Acts. The medical importance of this Bill is considerable, since the factory code is one of the greater arms of the spreading tree of preventive medicine. The student of factory legislation, as he peruses it, must inevitably think of the past great fights fought by Oastler, Lord Ashley, better known as Lord Shaftesbury, and others a century ago, of the opposition from political economists and the Manchester school, and of the great victories won to which we are heirs. In addition to consolidation the Bill proposes several important legislative advances. The old distinction between factories and workshops is to disappear, and also between textile and non-textile factories; a working week limited to 48 hours for protected persons is adopted; permission to use the shift system, which has been on trial since 1920, is included; work on the structure of ships in dock is brought within the Bill, and so are building operations—an important extension. In many directions provisions are strengthened in the light of administrative experience and are widened as, for instance, when workers are not merely forbidden to interfere with or misuse appliances provided for health, safety, or welfare, but have placed upon them the duty of using such appliances.

The medical profession will be particularly interested in two proposed variations in procedure. The first concerns the enforcement of sanitary conditions in workshops which is at present entrusted to local sanitary authorities. The new Bill transfers enforcement to the factory inspectorate, and over this matter controversy is certain to arise. On the one side the principle may be advanced that adequate enforcement with maintenance of the standard of equipment is best attained through the activities of expert inspectors who, moreover, are concerned with the other provisions of the measure, and have been in the past accustomed to deal with these provisions so far as all places, except workshops, are concerned; the principle is that of unification of inspection. Further, the inspection is entrusted to persons entirely independent of all local influences. On the other hand local authorities may claim that they should not only retain their present powers but have them extended to all places contemplated under the Bill; that the authority which is responsible for cleanliness, overcrowding, ventilation and drainage for all other purposes in a district should also control these matters in the factories of the district; that these are matters affecting the general health of the district for which they are responsible and calling for medical supervision rather than for non-medical inspectors; for only in this way can local authorities become acquainted with the way in which the industries of their districts are carried on. Their claims are logical since enforcement of all sanitation in each district would thus be unified. Presumably the Government departments concerned have come to agreement but medical officers of health, as representative of local authorities, may yet object that their view-point has not been fully considered. Possibly the balance for efficiency leans towards the procedure embodied in the Bill. But whatever be the final issue, the present system of dual control is unsatisfactory.

The second matter of particular interest to doctors concerns the medical examination of young persons proposing to enter on factory life of any sort. This work is laid down to be performed by "appointed doctors," and no allusion is to be found anywhere to the existing office of certifying factory surgeon, except where it is stated that under the Workmen's Compensation Act, 1925, references to a certifying surgeon shall be construed as references to an "appointed doctor." The provisions governing the examinations have been recast and strengthened while local education authorities are called upon to produce to an "appointed doctor" the school medical record of young persons, and this officer is defined to mean a medical practitioner duly appointed to act, the appointment resting usually in the hands of the Secretary of State or chief inspector. As he is to be appointed for individual factories rather than for whole districts, the assumption is reasonable that some choice of doctor may now be accorded to each establishment. His fees and duties may be determined by the Secretary of State, but contracts for service are not ruled out, nor is extension of duties beyond the examination of young persons—indeed the possibility of such extension seems adumbrated elsewhere in the Bill when power is taken to arrange by order for special medical supervision of workers, where the amount of sickness or some other reason renders it desirable. Somewhat unaccountably no power is given to an appointed doctor to inspect the work upon which a young person is to be employed; the omission ought to be rectified before the Bill becomes law. Taken as a whole while much must depend upon the way in which the scheme of appointed doctors is administered it seems to give opportunity for the development of an adequate factory medical service such as industry, in its own economic interests, to-day badly needs. In one direction, however, an interesting but not very promising innovation is allowed for by permitting the transference of the appointment and duties of an appointed doctor to a county council. Should use ever be made of this proposal a factory would lose any say in the personality of its appointed doctor, while any extension of duties for supervising the health of adults would carry the whole-time public health staff into a realm at present unexplored by it and might end in the creation of another blind alley service, in addition to those of tuberculosis officer and school medical officer. This may be due to some interdepartmental compromise, but the factory medical service will have a better chance if it be free from dual control.

The new Bill of which our Parliamentary correspondent makes a full abstract elsewhere, contains, among many useful health provisions, the power to secure sufficient and suitable lighting in factories and to insist on the precautions to be adopted in places where dangerous fumes accumulate—for example, in tar stills and boiler flues. It is a piece of useful and progressive legislation, the result of careful preparation. Unless profoundly altered by Parliament before being placed on the Statute Book, it will rank as worthy of a great legislative ancestry.

THE MICROSCOPY OF THE LIVING EYE.

THE eye is easily accessible and lends itself to objective examination because its media are transparent, slight subjective disturbances in function are regarded as important by everyone, and the consequence is that clinical investigation has reached a higher degree of exactitude in the eye than in any other organ Elsewhere the clinician reasons largely by inference, and medicine has to rely on morbid histology for the elucidation and interpretation of its clinical conditions While no one will deny the value of this indirect method of pathological investigation or the importance of post mortem lessons, undoubtedly they must give way to any technique which permits the direct study of pathological processes as they unfold themselves in the living tissues Ophthalmology has thus become the most exact of the branches of medicine, and each improvement in technique has given an immense stimulus to its progressive advancement The first of these advances may be said to have been the introduction of focal illumination by HIMLEY over 100 years ago, but the difficulties of the method and the limits of its effectiveness, on account of the indifferent optical appliances and means of lighting available at that time, set severe limitations on its immediate extension and value The second was the discovery of the ophthalmoscope by BABBAGE in the middle of last century, which, throwing open new and fruitful fields of study, was the prelude to the greatest activity that ophthalmology has ever known It is difficult and not a little dangerous to assess the ultimate value of contemporary events, but the introduction of the slit-lamp by ALVAR GULLSTRAND in 1912 bids fair to have begun a third epoch of stimulating progress, wherein old problems are being attacked and solved, new ones are being opened out, and a fresh perspective, presented with a precision hitherto unknown, is being unfolded

An account of the principles involved in the new method, and some of its practical applications, will be found elsewhere in this issue in the Montgomery lecture, delivered by Mr HARRISON BUTLER, who has done not a little to further this new branch of knowledge To the clinician practising ophthalmology the slit-lamp is invaluable, and what was a luxury yesterday promises to become a necessity to-morrow The fear that its complexity would necessitate its confinement to the field of clinical research and preclude it from routine practice is unfounded The expert—and it is within the powers of the average person to become to a very large extent an expert—in a period of time not much longer than it takes to read these lines, can bring successively into focus the corneal surface, its parenchyma and its endothelial layer, the aqueous, the intimate structure of the iris, the capsule, the complex configuration of the internal structure, the posterior surface of the lens, and the delicate framework of the vitreous These may be examined with an ease and precision hitherto unapproached, each presented with a wealth of detail, and localised in its true perspective in three dimensional space An additional complexity, the contact-glass, which is needed for examination of the posterior part of the vitreous and the retina, is unsuitable for the vast majority of patients, and in its present stage of development probably presents too many difficulties and takes up too much time to be of much clinical value The cornea, from its position and great transparency, is the structure most readily examined, but it is also the structure most amenable to detailed study by the older methods, and it is in the anatomy and pathology of the lens that the greatest increase to our knowledge has been made This tissue is found to have, optically, a most complicated formation, and cataract is found to be a disease showing many unsuspected different and well differentiated types The immense amount of data collected by VOGT and his co-workers during the last few years, which is being rapidly sifted and added to in this and other countries, is throwing new light on this condition With the slit-lamp the process of opacity formation can be detected in its most early stages before any change can be made out by the ophthalmoscope or any functional defect is noticed by the patient, exact localisation of its site and details of its structure can be obtained, a minute record of its progress can be made, and it is claimed that it is possible to reach some conclusion as to its probable rate of development and ultimate termination In many other conditions the observer can see fine points of diagnostic importance which could not formerly be made out at all or only with difficulty, or when they had reached a stage of development which we are now in a position to consider as gross these include slight vascularisation of the cornea, minute keratic precipitates, early opalescence of the aqueous, and small pigmentary remnants on the lens capsule The importance of their recognition can be realised when it is remembered that upon the presence or absence of such conditions rest some of the most grave decisions in ophthalmological practice

It is to be remembered, however, that the method has its well-defined limitations Enthusiasm for a new subject is apt to lead to an over-liberal estimation of its value Slit-lamp microscopy is merely an adjunct, a refinement, of the older methods of examination, it does not supersede but merely amplifies them, and it must be allotted not more than its due share in the general scheme of routine examination To rely upon its aid alone is to lose all sense of perspective, and to run a grave risk of misinterpreting the changes seen and of forming a wrong conception of their significance, it is to make the mistake of using the direct method of ophthalmoscopy without the indirect, of examining a microscopic slide with the oil-emulsion lens before the low-power objective Nor can the method supersede the study of minutiæ with the microscope The useful magnification is limited by the inability of the patient to maintain fixation, which places the slit-lamp outside the scope of cytological and bacteriological studies It provides no substitute for differential stains and reagents, and —what is often forgotten—the pictures it delineates are largely optical phenomena, capable of varying interpretation The interpretations of different observers are not always in accord, and long experience is required to form an adequate judgment on the finer points Many of the interpretations, now somewhat loosely accepted, will have to be revised, new appearances will be described, and new values put upon the old The study is still in its infancy, and it will be long before it has definitely established itself and given to us all the potentialities which it possesses To the clinician the slit lamp offers fresh opportunities for adding to the store of his knowledge pictures and conditions which are available by no other method, and it provides him with means for the easier and more confident detection of signs which may be of the greatest import at a stage at which they have hitherto been unrecognisable To the pathologist it discloses processes in significant detail as they occur topographically and unchanged by artefact, which are often without significance when considered post mortem as isolated findings To the anatomist it has opened up a new structure of the living eye; the anatomy of the lens is being elaborated at a pace which has made our most modern text-books obsolete, and ten years ago the structure of the vitreous was unknown To the embryologist it has given a new conception of the embryonic remnants, to the physiologist of the eye it gives new scope for the study of the activity of the pupil and the mechanism of accommodation, but by the general physiologist it seems to have been so far neglected. As far as we are aware no serious attempt has been made to turn to experimental purposes the physiological possibilities offered by observation, under microscopic magnification, of nerve-fibres or newly formed capillaries in the substance of the cornea, or of normal capillaries in the conjunctiva near the limbus in their natural surroundings We think we are right in saying that COCCIUS was the first in 1852 to study the minute limbic vessels and to observe the circulation in them, but this work seems to have been largely forgotten They are easily examined, their dilatations and contractions and periods of complete obliteration the stream of corpuscles within them progressing by pulsations, now proceeding and now stopping, just as described by KROGH and others in less accessible surroundings, are very evident New-formed vessels also, composed of a single endothelial layer and showing pulsatory activity, can be induced to wander into the transparent cornea after an inflammatory lesion The study of these, by means of the slit-lamp, in their natural environment, and the study of their reactions to stimuli and to drugs, might be useful in a branch of physiology upon which much attention is being focused

◆

ACID MILK IN INFANT FEEDING

THE recent minor heat-wave was associated with the usual sporadic outbreaks of acute gastro-intestinal disorder in infants, and serves to remind us that though many of the ætiological factors in such diseases are now more clearly understood than formerly, the story of their pathogeny remains far from complete The growth of the infant welfare centres has done much to diminish epidemics of summer diarrhœa, but the therapeutic problems in individual cases remain hard to resolve On page 322 of our present issue we publish an article by Dr. ETHEL CASSIE and Dr. URSULA COX recording results obtained at the Carnegie Institute, Birmingham, by the use of lactic acid milk in the feeding of babies suffering from wasting and gastro-intestinal symptoms In the first part of this article the writers discuss the factors governing the acidity of the gastric contents in infants. The problem is a difficult one owing to the limitations imposed on the observer in the choice of test-meal, and the necessity for avoiding the too frequent passage of stomach-tubes; the conclusions of the authors have consequently been given with considerable reserve The second part of the article deals with their clinical experience with sour milk feeding It must be noted that a preliminary trial of more orthodox methods eliminated the majority of simple cases, leaving a number of obstinate ones The success of the treatment shows it to be worthy of extensive trial, and we hope that these observers will soon be in a position to publish results from a larger series of cases, with fuller investigation of the nature of the changes in the intestinal flora which may occur as the result of feeding with milk thus impregnated with *B bulgaricus* It is still uncertain whether bacterial replacement is a feasible proposition, but the observations of most workers tend to show that milk for such purposes must always be prepared in the laboratory and that trade preparations claiming to yield cultures of *B bulgaricus* and *B acidophilus* are for the most part inert and useless Readers interested in this subject will find it admirably reviewed in a recent work[1] by N. KOPELOFF. Working chiefly with asylum inmates, he was able to relieve obstinate constipation almost without exception by giving daily doses of milk containing cultures of *B acidophilus* The results in cases of chronic diarrhœa were often extremely encouraging, though by no means so certain Bacteriological investigation of the fæces of these patients showed that it was necessary to give the milk cultures over rather long periods in order to obtain a free growth of *B acidophilus*, though subsequent arrest of treatment finally led to the organisms disappearing from the stools, this did not happen for a considerable period The bacterial flora of the intestine presumably may take some time to reach equilibrium after the introduction of a different type of organism, in somewhat the same way as the smooth working of a sewage purification system requires a few days to adjust after the introduction of the appropriate bacterial sludge, although, when equilibrium has been established, the process continues unchecked for an indefinite period without further interference. From the theoretical point of view there is little doubt that bacterial implantation offers immense therapeutic possibilities, and it is to be hoped that the next few years may see an increase in the clinical and experimental study of the subject. Relevant to this subject is the increasing vogue of milk pasteurisation to which Mr T. MCLACHLAN draws attention in an important letter in our present issue. Dr. ERIC PRITCHARD has stated more than once that his chief objection to the indiscriminate use of commercially pasteurised milk is the selective lethal influence which pasteurisation has on the bacterial flora, and this point is emphasised by Mr. MCLACHLAN. Dr. PRITCHARD laments our ignorance of the significance of a mixed bacterial flora in the alimentary tract. We hardly know, he has said, what is normal and what is not At the Infants Hospital, however, although the milk-supply is beyond reproach, a practice is made nevertheless of souring any milk which is supplied to premature or young babies who are not breast-fed Current American practice does not go as far as that, for Dr C G. GRULEE, one of the recognised experts in infant feeding, stated in a recent address[2] that acid milks are necessary in only 1 in 300 cases of infant feeding

RESEARCH IN BREEDING ANIMALS—The Rockefeller Foundation has offered £30,000 for the extension of the Animal Breeding Research Department at Edinburgh on condition that an equal sum is raised in this country The International Education Board is said to have come to the conclusion that this department, which is under the joint management of the East of Scotland College of Agriculture and the University of Edinburgh, is the best centre in the world for training in agricultural genetics. The donation is offered so that it may be able to provide for the training of students from all parts of the world The department is under the direction of Dr F. A. E Crewe and during the past year courses of lectures have been given by members of the staff to students of agriculture and veterinary science at many centres in England and Scotland.

Annotations.

"Ne quid nimis"

PRACTITIONERS AND DANGEROUS DRUGS.

Effect has now been given to the recommendation, made by the Departmental Committee on Morphine and Heroin Addiction, that a medical tribunal should be set up to consider the case of medical practitioners addicted to drugs or supplying them for purposes of addiction As already foreshadowed,[1] this tribunal is to consist of three medical practitioners, assisted by a legal assessor, and as from July 29th last the Home Secretary is no longer obliged to chase an offending doctor into the police-court in order to obtain the withdrawal of his authority to supply and possess habit-forming drugs It was the feeling of the Departmental Committee that a tribunal with a strong medical element would serve the double purpose of protecting from himself a doctor who had unfortunately become a drug addict and protecting his patients by preventing him from prescribing dangerous drugs in excess The new Regulations will achieve this purpose and at the same time avoid unseemly publicity in a distressing but happily very small class of cases The other Regulations which came into force on the same date make it an offence for a person to go to a second doctor for a supply or prescription of habit-forming drugs unless he first discloses that he has been receiving treatment from another practitioner Doctors, dentists, and veterinary surgeons are now required to keep records of all supplies of dangerous drugs purchased or obtained by them, whether or not they dispense or otherwise supply the drugs Copies of these Regulations, amending the Dangerous Drug Regulations of 1921, are obtainable from H M Stationery Office.

GASTROSCOPY

There is significance in the fact that endoscopic examination of the stomach was being attempted in London before the war, whereas to-day the practice is so rare as to be almost unknown. The difficulties and dangers of the procedure have caused it to fall into abeyance Nevertheless, it is still employed quite frequently both in Germany and in Austria, and it seems clear that if it could be brought to a more perfect state of technique it would be of the utmost importance both in diagnosis and for watching the effects of treatment When we realise the immense issues determined by the examination of an X ray shadow the potential value of a direct view of the gastric mucosa is apparent Stimulated by such views Dr. Jean Rachet,[2] working with Dr Bensaude at the Hôpital Saint-Antoine in Paris, has recently published a study of his clinical and experimental observations with this instrument The modesty and logic of his conclusions are such that we feel them worthy of reproduction here Gastroscopy must remain an exceptional method of gastric examination, it occupies a position in the means at our disposal after radiographic examination but before laparotomy Gastroscopy demands the exercise of the greatest prudence, the greatest patience, and the greatest gentleness The method cannot be looked upon as an everyday means of investigation and should remain in the hands of experts trained in its use The safety of its employment must not be sacrificed even for the benefit of progress It is impossible with a gastroscope to explore the whole of the stomach and consequently a negative finding does not permit of the exclusion of organic disease A straight, rigid gastroscope for indirect vision is advocated by Dr Rachet, and he insists on the importance of scrupulous preliminary examination of the patient The passage of the instrument is made with the patient in the position of left lateral decubitus, local anæsthesia is employed, and a guiding thread is first swallowed by the patient After detailing the technique necessary to obtain an adequate view of the greater part of the stomach, the author points out the value of the method for studying recent peptic ulcers and for identifying early malignant growths As regards the latter, he notes the disappointment that must result from the fact that patients experience symptoms so late that even by the most accurate means of diagnosis early cancer will rarely be discovered In the study of true gastritis the instrument holds out hope of progress in our knowledge, for it is only when direct vision is added to our armamentarium that we can hope for any real advance concerning this disease "Gastroscopy," Dr Rachet concludes, "appears to be a method promising rich results, but it requires great prudence and much further research to establish its final value It should in no case supplant other means of investigation, and it is by the accumulation of clinical facts that it will acquire its right to be quoted as a first-class means of examining cases of digestive disturbance"

MEDIÆVAL MEDICINE

An excellent epitome has been made from the four volumes already published of Mr R T Gunther's larger work, "Early Science in Oxford," in order that a large number of students for whom the cost of the original book was prohibitive may have an opportunity of studying some of the subjects therein mentioned The present work[1] is in seven chapters dealing respectively with Early Medicine, Medicine in the Seventeenth Century and After, Anatomy, Physiology, Zoology, Botany, and Geology The book is of a size handy to read, admirably printed, has many illustrations, and is altogether delightful Mr Gunther has a wonderful flair for extracting gems from the various ancient mines in which he has been working, and many of them show how true is the aphorism that there is nothing new under the sun For instance, the following excerpt, taken from the diaries of one Simon Forman (1552–1611), of Magdalen College, puts modern professors of rejuvenation in the shade "and myselfe did boill 2 snakes in my strong water when I distilled it and after I drank of that water and yt made me to be fresh and take away all my gray hairs when I was 56 yers old and many toke me not to be above 40 or 42" Another would, if he reads it, make Sir Arthur Conan Doyle extremely envious It concerns a Fellow of Trinity, by name Th Allen (1542–1632), noted for his skill in mathematics and astrology The vulgar looked upon him as a magician and his servitor would tell them "that he met the spirits coming up the stairs like bees" Few outside the medical profession, or we might even say within it, know that the architect of St Paul's was the same Dr Christopher Wren, Fellow of All Souls, to whom are due the beautiful anatomical drawings in illustration of Willis's work on the brain, and that he was also the originator of intravenous injections The discovery of a method of injecting bodies with a solidifying fluid is due to Boyle, as also the method of keeping moist anatomical preparations in spirit Richard Lower, a pupil of Willis, studied the anatomy of the heart (1669) and left some accurate drawings of the muscular fibres, showing the spiral arrangement of the muscular fibres, a fact almost forgotten until its revival by Pettigrew Robert Hooke, of Christ Church (1635–1702), who was not only a skilled microscopist but an architect of no mean talents (he built the new buildings of Bethlehem Hospital in 1675), was the first to record that the blue colour in a peacock's tail has no real existence, but is due to "a texture visible under the microscope"—i e, is due to interference, though, of course, he did not know the reason These quotations may suffice to indicate the interest of Mr Gunther's book Of the series of postcards issuing from the same press,[2] two especially are worthy of note, the one (dated 1631) shows the Castle of Health attacked by flying evils, an early forecast of microbial invasion, the other (dated 1660) is an amputation scene from a window in the Bodleian The patient is seated in a chair placidly regarding the operator, who is removing his leg with a hack-saw, no preliminary incision of the soft parts having apparently been made

THE ACTION OF PITUITARY EXTRACT ON THE UTERUS

IN 1924 Dixon and Marshall[3] showed the existence of a relation between the cyclic activity of the ovary and the pituitary gland, and stated that the amount of pituitary secretion discharged into the cerebrospinal fluid depends largely upon whether corpora lutea are present or absent They came to the conclusion that as the corpus luteum is supposed to undergo retrogression shortly before the close of pregnancy, the revival of the ovarian secretion causes a sudden increase of pituitary secretion, which by its action on the more irritable uterine muscle brings about labour According to this theory the increase of pituitary secretion is an important factor in starting parturition Subsequent observers, in studying the conduction of contractions in uterine muscle, found that there are distinct changes in the mechanism of this muscle at different stages of the œstrous cycle It was also found that remarkable changes take place under the action of pituitary extract, which seems to induce the same effect in the uterus at the diœstrous period as that which occurs naturally at œstrus and during early pregnancy In order to test the view that a steady or sudden increase of pituitary secretion at the end of pregnancy finally brings about labour, H H Knaus[4] has now reported on his further results obtained from injecting standardised pituitary extract into doe rabbits at various stages of pregnancy The duration of pregnancy in these animals is 31–32 days It was found possible to induce parturition by injecting a certain quantity of pituitary at any time after the twenty-ninth day of pregnancy. In experiments during the time from the eighteenth to the twenty-eighth day of pregnancy no quantity of pituitary was found sufficient to induce abortion on the day on which the experiment was carried out, but as a result of prolonged pituitary action—nine injections of pituitary were given at hourly intervals—the fœtuses were killed inside the uterus, and were cast some days afterwards In a group of experiments covering the period from the first to the seventeenth day of pregnancy, no matter what (reasonable) quantity of pituitary extract was injected, it was never found possible to disturb pregnancy Knaus considers that his results show that considerable changes occur in the relation between the hypophysis and the uterine muscle during pregnancy An interpretation of the results might apply to one of these organs or to both of them. He concludes that there is no increase of irritability or sensitivity of the uterus during pregnancy, but that, corresponding to the growth of each muscle cell, there is a regular rise of contractility of the muscle The larger the muscle cell the greater is its ability to shorten itself, and that is why the effect of pituitary extract upon the muscle increases steadily and pregnancy advances By the twenty-ninth day of pregnancy the uterine muscle cells have grown so large that their maximum contraction, caused by pituitary, results in delivery of the young, while in the last few days of pregnancy the uterus keeps on growing and increasing its contractility, so that eventually a maximum contraction is no longer needed to produce the young

RESPIRATORY ARCHIVES

THE first number of a new journal entitled *Archives Médico-Chirurgicales de l'Appareil Respiratoire* has just reached us, founded by Emile Sergent and Th Tuffier, its object being to collate the work of physiologists, physicians, and surgeons in its bearing on the pathology of the respiratory system The founders hold that recent knowledge of the physiology of the chest and precision in technique have given a fruitful stimulus to the clinical study of respiratory diseases and have contributed largely to the development of new clinical methods Artificial pneumothorax, phrenicectomy, and extrapleural thoracoplasty enable the physician to-day to contend against lesions thought, until recently, to be almost incurable Excision and destruction by cautery of lobes of the lung involved by suppurations or by tuberculosis are no longer considered in the light of forlorn hopes Each number of the journal (about 100 pages) is to comprise three parts, the first to be reserved for original contributions, the second for critical reviews, and the third for a digest of the principal papers published in France or abroad The *Archives* will appear at two-monthly intervals, the cost in England per volume of six numbers being 130 francs The publishers are Gaston Doin et Cie, Paris

The first number opens with an article by E Sergent on the interpretation of respiratory murmurs, in which he pleads for recognition of the fact that a pathological breath sound is not something adventitious or superimposed, as are râles and friction sounds, but is none other than the physiological laryngotracheal sound, transmitted by some pathological cause beyond those regions over which it is normally perceived and modified in its acoustic properties by the physical conditions associated with the pathological cause In the second original article Th Tuffier, to whom every credit is due for the origination of this method, deals with extrapleural pneumolysis which he has himself carried out 57 times in 55 subjects, 44 of whom were suffering from pulmonary tuberculosis He used fat grafts in 33 cases, paraffin in 8 cases At first sight his results appear happier than those obtained by other surgeons, but many of his observations are of short duration For example, while one case was seen eight years and another two years after operation, and both had done well, in 11 other cases of pulmonary tuberculosis reported as satisfactory an opinion was based on examinations made less than five months after operation The results in cases other than tubercle were less satisfactory Phrenicectomy is the subject chosen for critical review F Bordet discusses the results obtained in cases (1) of pulmonary tuberculosis, (2) of bronchiectasis, (3) of chronic basal suppurations In the first group the scope of the operation as a curative measure is very limited, although in Germany, Italy, and America improvement has been claimed in a number of cases As a preliminary to thoracoplasty, and in association with artificial pneumothorax, phrenicectomy is gaining adherents The curative value of phrenicectomy as the sole procedure in the treatment of bronchiectasis is regarded as doubtful, though there have been exceptional cases A Baumgartner and P Alary deal with the possible variations in origin and course of the phrenic and accessory phrenic nerves They favour the operation of evulsion (exeresis) over the radical operation of Goetze except in cases where difficulties arise and particularly when there is pleural effusion They do not discuss the difficulties caused by pain and transmitted pulsation during evulsion, which are very real to those who have had experience of the operation It is surely optimistic to state "When one has resected 7 or 8 cm of the phrenic at the base of the neck one can consider that the anastomoses have been destroyed"

The journal has been modelled on the well-known *Journal de Chirurgie*, and the idea and its execution are both excellent. It remains to be seen whether sufficient material can be produced in one country to maintain the output at a high standard.

A SEPTEMBER POST-GRADUATE COURSE FOR PRACTITIONERS

A COURSE of instruction for qualified practitioners will be given at St. Bartholomew's Hospital during the summer vacation, beginning Monday, Sept. 6th, and ending Saturday, Sept. 18th. The object in view is to afford practitioners the opportunity of attending the practice of a large metropolitan hospital and medical college for a short period and of receiving systematic teaching from members of the hospital staff at a time when ordinary lectures and classes are in abeyance and comparatively few students are in attendance. The course includes the usual rounds of the physicians, surgeons, and specialists on the hospital staff, as well as demonstrations in the wards and in the out-patient departments. There will also be a series of special demonstrations on such things as the clinical significance of gastric secretion, carcinoma of the tongue, amputations in relation to artificial limb-fitting, the diagnosis and treatment of chronic sepsis of the lung and pleura, infections of the urinary tract, sanocrysin in pulmonary tuberculosis, artificial sunlight in general medicine, and regional and local anæsthesia. Practitioners attending the post-graduate course become temporary honorary members of the Students' Union and have the use of the Abernethian smoking and writing rooms and of the dining room. The composition fee for the whole course is 10 guineas, reduced to 8 guineas for practitioners who are perpetual students of the hospital, while either week of the course may be taken for the fee of 6 guineas (5 guineas). Every practitioner who enters for a course is required to call on the Dean and to sign the hospital register. Application should be made to the Dean, Dr. T. W. Shore, St. Bartholomew's Hospital Medical College, London, E.C. 4.

A NEW DUST TRAP FOR ROCK DRILLING

THE introduction of the percussive or pneumatic drill for carving granite and for boring holes in rocks into which explosive charges are inserted has added greatly to the dust danger of granite workers and miners, more particularly when the rocks contain silica, as in the case of granites and many metalliferous lodes. Many efforts have been made in the past to control the escape of the dust by the use of water either through hollow drills or by sprays, but they have proved little more than palliatives, and the incidence of silicosis has gone pari passu with increased use of the drills. Now, however, the welcome announcement is made from the Mines Department of an ingenious device for trapping the dust as it is formed.[1] It is sucked away from the place where the drill enters the rock by an exhaust draught which is actuated by spent air escaping from the drill. This air is made to pass off by a nozzle placed within a larger pipe when, on the ejector principle, it induces a considerable suction of air into the pipe. The more the drill works, the more does spent air escape to induce a greater exhaust draught for catching the dust, since the pipe is made to open where the tool is at work. The exhaust draught carrying the dust is discharged into a flannel trouser, the bottom of which fits on to an open metal box. The air escapes readily through the flannel leaving the particles of dust behind. These particles are automatically shaken off the flannel down into the box by the pulsating nature of the exhaust draught due to successive puffs of spent air escaping from the machine drill. The device only comes into play when the drill is in action and makes use of semi-compressed air which was otherwise wasted. For catching dust when holes are being blown out the ejector nozzle is attached direct to the compressed air supply. The efficiency of the device has been demonstrated by comparative dust counts which indicated from 58 to 198 dust particles per cubic centimetre of air with no work in progress, over 2000 particles (too many to count) with the drill at work without the device, and 163 to 332 with the device attached. In the South African gold mines the standard of safety adopted for dust concentration is 300 particles per cubic centimetre of air. This device may confidently be expected to save many lives from silicosis, and to go far towards banishing from the rock-drill the insidious and terrible risk which has always been associated with its use.

IN DEFENCE OF THE TOOTH-BRUSH

IN the *Scalpel* of July 10th Dr. F. Watry combats the indictment of the tooth-brush by Dr. M. Polet in a recent number of the *Annales de l'Institut Chirurgical de Bruxelles*. Dr. Polet accused the tooth-brush of being a cause of dental caries, gum trouble, and pyorrhœa, and would have us trust instead to thorough mastication, fruits especially apples and fibrous roots at the end of a meal, and rinsing of the mouth. He also advocates the use of liquorice root as a substitute for the tooth-brush. Dr. Watry claims, on the other hand, that the tooth-brush is invaluable as a weapon of oral prophylaxis, and that the harm is done by badly constructed tooth-brushes, generally dirty, and used in the wrong way. Very few people, he says, have such perfect mouths as to justify dispensing with the tooth-brush. The brush should have a light impermeable handle and the bristles should be arranged so that they will clean the dental interspaces and so that they can be readily cleaned and disinfected by allowing water or disinfectant vapour to get between and around them. The brush should be suited to the individual mouth and, if possible, chosen by a specialist. It should be disinfected before its first use and cleaned and sterilised after each subsequent use. Boiling is not possible but formalin vapour may be used. Dr. Watry admits that among the masses one will have to be content with careful washing and keeping in a clean place. Before using the brush the mouth should be thoroughly rinsed and gargled. The brushing should be vertical, from below upwards for the upper jaw, from above downwards for the lower jaw with an energy suited to the tone of the tissues, so as not to cause bleeding. Thorough rinsing and gargling should follow the brushing. It is a good plan to follow the brushing by the use of a thread to clear the interdental spaces. Some experts also recommend massage of the gums with the fingers. These rules do not apply to mouths in a pathological or inflammatory condition, in which event medical advice should be sought.

There is no reason to apprehend trouble owing to the moving of the buccal flora from one part of the mouth to another by a clean brush. The substitution of liquorice root for the tooth-brush cannot be considered an advance. Dr. Polet's paper, says Dr. Watry, will serve a useful purpose by drawing attention to the abuse and clumsy use of the tooth-brush. Dr. Watry reminds us that the International Dental Federation, under the presidency of Prof. Brophy, of Chicago, instituted more than a year ago a thorough inquiry into the question of the tooth-brush. The special committee appointed to conduct the investigation has not issued its final report but it made a provisional report to the Federation at the Geneva meeting of 1925. The provisional report confirms the value of the tooth-brush and attributes the harm imputed to it to its wrong use or to the use of unsuitable brushes, and attaches great importance to the education of the public as to the proper construction and use of tooth-brushes. The committee also proposes to go fully into the question of the alleged harm done by tooth-brushes, however small it may be.

LIGHT AND VITAMINS

LIGHT is gradually being shed on the nature of the vitamins by the agent itself It has already been shown by Hess and Weinstock that vitamin D is a photosynthetic body, being, in fact, built up by the action of light on cholesterol, and the observation has more recently been confirmed by Steenbock. In an interesting note from the Middlesex Hospital by Dr P. R Peacock, which we publish this week, it is shown that vitamin A is photolabile—that is to say. it is destroyed by light, provided that the light is of sufficient intensity Dr Peacock noticed that cod-liver oil lost its fluorescence when exposed to light for months on the working bench, and he set himself to discover whether its "delumination," as he calls it, bore any relation to the vitamin content of the oil He soon found that the deluminated oil failed to show the usual chemical test for the presence of vitamin A, but on following the matter up he discovered that delumination and destruction of this vitamin were parallel but not identical phenomena. since fully deluminated oil recovered its fluorescence when kept in the dark, although the colour test for vitamin A failed to return On the other hand, he found no evidence to suggest that the antirachitic vitamin D in cod-liver oil is destroyed by sunlight Light, he concludes, is thus a variable factor which must be taken into account in estimating the growth-promoting properties of cod-liver oil and attention must be paid to the manner in which the oil is stored While the essential chemical nature of the vitamins still remains obscure, observations such as those of Dr Peacock may serve to indicate into what categories they fall, and even to suggest types of molecular stability. There are apparently two changes in the absorption spectrum of cod-liver oil after exposure to light, one corresponding to the destruction of vitamin A and the other indicating a chemico-physical change of a reversible character. Such reversible changes initiated by light are on our present knowledge extremely rare, and it would be premature to state definitely that the changes observed are purely chemical in character Further researches on this point would be of great interest

HERITABLE HYPERGLYCÆMIA

WHEN hygiene begins to take eugenics seriously it will have no task more important than the identification of heritable characters and their modes of grouping and inheritance A knowledge of the possibilities and what is worth looking for in man must almost necessarily be derived from the study of some shorter-lived animal; the valiant contributions which thousands of mice have made to our knowledge of cancer before they died of old age, at about 2, have been extraordinarily useful, and it is in these same handy animals that Dr. P J. Cammidge and Mr H A. H Howard have made some highly suggestive observations on blood-sugar [1] In the ordinary run of mice the fasting concentration of blood-sugar is about 85 ± 5 mg. per 100 c cm A certain number show, however, substantially higher figures, ranging round 120 mg , and if these are bred together all the progeny have hyperglycæmia too Further appropriate matings showed that high blood-sugar is inherited in a straightforward way as a Mendelian recessive character and the results of crossing high with low and low with low depended on the genetical constitution of the animals exhibiting the dominant low character Incidentally the breeding experiments involved albinism—another recessive character—as well, and they show that the two are inherited independently of one another It will be of much interest to see whether these results apply also to man; they probably do Published collections of normal blood-sugar figures by H Gray[2] show a distribution of values in a tolerably normal curve without any suggestion of two modes But recessive characters are shy and especially if they involve a greater liability to death or a lesser likelihood of reproduction than normal. they may be obviously present only in a very small proportion of the population, as, for example, is feeble-mindedness What relation hyperglycæmia has to diabetes is uncertain It seems extremely probable that diabetes is usually caused by the wearing out by overwork of a congenitally weak mechanism for disposing of carbohydrates Hyperglycæmia is naturally an early symptom, but it cannot at present be affirmed that it is causally related to actual diabetes A heritable factor has been involved in the ætiology, as indeed it has in most diseases of which the cause is not known, but definite evidence is lacking, though diabetes insipidus is sometimes clearly inherited. Those who doubt the hygienic importance of tracing out as diligently as it can be done the facts of human inheritance should study the memoir on the relative factors influencing infant welfare by Dr. Ethel Elderton which is appearing in the *Annals of Eugenics.* Poverty, housing, and sanitation have little effect on infant mortality, compared with the influence of the father's health and habits and especially of the health of the mother. Whether health and habits cause environment or vice versa is as yet unsolved, but the general impression given by Dr. Elderton's work, expressed in terms less guarded than her own. is that the nature of the people concerned is more important than their surroundings and that their nature is inborn Parallel results are recorded by Prof. Noël Paton and Prof Leonard Findlay in their report on Poverty Nutrition, and Growth, reviewed in THE LANCET, July 31st, p 240. In this report similar emphasis is laid on hereditary as opposed to environmental factors as influencing the growth of children in slums

[1] Jour. Genetics 1926 xvi, 387.

[2] Arch Int Med, 1923 xxxi, 241

WE regret to learn of the death of Dr Robert Henry Cole, physician for mental diseases to St Mary's Hospital and last year's President of the Section of Psychiatry of the Royal Society of Medicine. Dr Cole succumbed on Tuesday last to an attack of angina pectoris.

AN Order of Council has been issued altering the composition of the Committee of Privy Council for Medical Research, the ministerial body under which the Medical Research Council conduct their work. The Committee originally consisted of the Lord President of the Council, the Minister of Health (England and Wales), the Secretary for Scotland, and the Chief Secretary for Ireland, but the last-named office has become obsolete as a result of the changes in the government of Ireland In view of this vacancy, and of the increasing relation of the Medical Research Council to research work in overseas parts of the Empire and in industrial medicine, the Secretaries of State for Home Affairs, for Dominion Affairs, and for the Colonies have now been added to the Committee.

INDEX TO "THE LANCET," VOL. I., 1926

THE Index and Title-page to Vol I , 1926, which was completed with the issue of June 26th. is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street Strand, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now

METROPOLITAN ASYLUMS BOARD —A three months' course in hospital administration is to be held for the benefit of candidates for the Diploma of Public Health, at the North-Eastern Hospital, St. Ann s road Tottenham London N, by the medical superintendent, Dr F H Thomson The lectures will be given on Mondays and Wednesdays at 4 45 P.M., and on alternate Saturdays at 11 A.M., and will begin on Oct 4th Application should be made to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C 4.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLXXXV

THE TREATMENT OF ANKYLOSTOMIASIS

FOR all practical purposes human ankylostomiasis may be defined as the sum of the effects of infestation with *Necator americanus* and *Ancylostoma duodenale*, one or both. Its treatment consists, first, in the poisoning and expulsion of all hookworms; and, secondly, in the counteracting of the ill-effects, particularly the anæmia, which they have produced.

The ideal anthelmintic would, in a single dose, kill all hookworms without endangering the host. No such drug is known. Accordingly, the dose of an anthelmintic drug is a compromise between efficiency and safety. Safety is mainly determined by the size of the dose; efficiency is presumably dependent upon the amount of the drug which comes into contact with the worms—that is to say, upon its concentration in the intestine—provided this be maintained for an adequate period.

With a view to intensifying this concentration it has become an established practice that, before giving an anthelmintic, the bulk of the intestinal contents shall be reduced by preliminary fasting and purgation. It will, however, be seen presently that this accepted procedure may be dangerous. It is a common practice to administer the anthelmintic in two or three equal fractions, generally at hourly intervals and in the early morning. Subdivision presumably lessens the intestinal concentration, but may increase the period over which the drug is present there in a degree poisonous to hookworms. It is further the practice to give a purgative with or after the anthelmintic, with the twofold object of eliminating the residue of the drug, thus lessening unwanted absorption by the host, and of removing the worms before they can either reattach themselves to the intestinal mucosa—should the poisoning be temporary and not fatal—or damage the host by absorption of any toxins which may be liberated by their dissolution. The purgative commonly takes the form of 16 to 32 g. of sulphate of soda or magnesia an hour after the last dose of anthelmintic.

Five Lines of Treatment.

Various lines of treatment have been advised for ankylostomiasis; of these five have obtained a vogue. They are—chloroform and eucalyptus, beta-naphthol, thymol, oil of chenopodium or its active principle, ascaridol, and carbon tetrachloride. Their anthelmintic value has been estimated (1) by post-treatment examination of the stools for ova (either crudely, for their presence at all, or accurately—and rarely—for the degree of their diminution in a unit quantity of solid fæces), or (2) by determining the percentage of worms expelled by any treatment compared with the total number expelled, both by the treatment under test and by a second treatment with a drug believed to be reasonably effective. The last year or two have shown that, as ordinarily carried out, both these tests are inaccurate. Accordingly, our knowledge of the efficiency of all lines of treatment is much less exact than it can, and it is hoped will, be made during the next few years, if what appear to be reliable forms of control are more widely adopted. Regarding the lines of treatment mentioned above, the position is as follows:—

Oil of Eucalyptus and Chloroform.—This treatment, at one time popular, consists of oil of eucalyptus 2.5 c.cm., chloroform 3.5 c.cm., castor oil 40 c.cm. The consequent symptoms have so often been provocative of anxiety that it now finds no advocates, at least for mass treatment.

Beta-naphthol, taken in excess, gives rise to vomiting and marked destruction of erythrocytes with the usual concomitants—namely, jaundice with hæmaturia or albuminuria—followed, it may be, by death. Such fatal consequences have been produced by a dose as small as 4 g. (R. Howard). Two deaths and a number of anxious cases have been produced among about 1000 persons taking an ordered dosage of 50 gr. (3.6 g.), the officer responsible questioning, however, whether they had received even as much as this. The drug in this instance was reported as being chemically pure. The optimum dose has been taken as 2 g., but even in this dosage there is clearly blood destruction since, as Ashford and Igaravidez have shown, it is invariably accompanied by the appearance of the diazo-reaction in the urine. As regards efficiency R. Howard, using the crude diagnostic methods available in 1918, reported that 9, 12, or more doses of 3 to 4 g. were required to disinfest. The best reported results appear to have been obtained by Ashford and Igaravidez, who continued treatment, with search of the stools for worms, so long as any were recovered. Of the total so found, 72 per cent. were recovered after the first treatment. In about 1000 cases similarly treated in India in 1916, and using the crude diagnostic methods then available, I found 25 per cent. still showing ova after five treatments.

Thymol has had a wide use in the treatment of ankylostomiasis. Its optimum dose is 60 gr. There seems to be no record of death with certainty attributable to thymol taken in optimum dosage. Vomiting, dizziness, and tinglings may be experienced. Including treatments and re-treatments, the writer gave about 50,000 optimum doses of this drug to some 20,000 persons in Darjeeling, India, without mortality or serious anxiety. It is the drug with the best record for safety. Regarding efficiency, Ashford and Igaravidez, using the methods already indicated, obtained from the first treatment 77 per cent. of the total worms recovered. It is thus somewhat more efficacious than beta-naphthol, but is more expensive. In the doses suggested as optimum, thymol produced no destruction of erythrocytes. It is apt to ball when given in powder form, considerable masses being found unchanged in the fæces. This wastefulness can be prevented by using powdered thymol and mixing it intimately with an equal quantity of sugar of milk, or the cheaper bicarbonate of soda, the kind of "adulterant" used being perhaps immaterial provided it mechanically separate the thymol crystals. Judged by the crude diagnostic methods available in Trinidad in 1915, this "adulteration" raised the cure rate after one treatment from 12 per cent. to 48 per cent. Thymol is soluble in alcohol and in oil. To avoid unnecessary risk of absorption these should be interdicted during treatment, the final purge not being castor oil.

Oil of Chenopodium.—The optimum dose of this oil was originally placed by Schüffner and Vervoort at about 48 drops, as furnished by the International Drop Counter, a total equivalent to about 1.2 c.cm. The measure has been misunderstood and the drop held equivalent to a minim, so that the dosage widely used has been 3 c.cm., and a number of deaths have followed. The toxic symptoms produced are epigastric heat, colic, nausea and vomiting, paræsthesiæ of all senses, weakness, incoördination and spasm, confusion, delirium, coma, and convulsions. Unaware of the actual position the experience of Darling and others reduced the dosage to 1.5 c.cm., which approximates to that from which Schüffner and Vervoort had never deviated. There seem to be no adequate figures available for the comparison of thymol and oil of chenopodium in their optimum doses. Darling compared 4 g. of thymol with 1.5 c.cm. of oil of chenopodium, and obtained relative efficiencies of 88.6 and 93.7 per cent. With the oil given in dosage of 1.2 c.cm. there is likely to be little to choose between the two drugs in efficiency or risk, and for mass work the choice will depend on convenience and cheapness of purchase and administration. This statement applies to

N americanus For *A. duodenale* chenopodium appears to be the more effective drug Its active principle, ascaridol was found by Nelson to comprise 50 to 70 per cent of the oil, and it has been stated that on keeping, the drug loses in efficiency and gains in toxicity When given mixed with castor oil it is less efficacious than when the purgative follows.

Carbon Tetrachloride, the popular anthelmintic of the hour, was introduced by Maurice C Hall in 1921 in dosage of 3 c.cm With this dose its efficacy is marked · and a number of deaths have occurred It seems definitely established that the chemically pure drug in this dose may kill with entire unexpectedness. The main lesions produced are fatty degeneration, with a subsequent necrosis, greatly aggravated by fasting of liver and kidneys—regeneration particularly in the former organ, being very rapid. Symptoms of poisoning include early nausea, vomiting, and epigastric pain, hepatic tenderness jaundice hæmaturia, and temporary suppression of urine. Hall and Cram point out that almost all deaths have followed what they call "therapeutic doses" and conclude that the drug has no minimum lethal dose. I would put the matter otherwise and suggest that the accepted is neither a therapeutic, nor the optimum, dose. Regarding a smaller dose, Smillie and Pessoa treated 15 cases with 1 5 c.cm. of the drug in two doses, and estimated that 62 per cent. of worms were removed and 12 5 per cent. of persons disinfested Even with this lessened dose one of their cases became gravely ill, with vomiting, much bile in the urine and a temperature of 104° F Straub and Kouwenaar, after 16 deaths with dosage from 1·5 to 3 c cm., disallow treatment by this drug. The drug may then kill with unexpectedness in doses of 1 5 c cm, in which dose it is less effective than are the older anthelmintics. Preliminary fasting increases risk of poisoning, as does ingestion of fats: glucose lessens it.

Carbon Tetrachloride Combined with Oil of Chenopodium or Ascaridol—A combination of these drugs has latterly been used in the hope that, their toxic effects falling largely upon different systems, the combination will be more effective than would either drug be separately, while toxicity will not be materially increased The efficacy of this combination merits, and will no doubt receive, a properly controlled trial

Conclusion.

From these considerations the following conclusions naturally emerge. If one place safety first and there is surely no possible justification for any other general attitude on the part of a medical man, carbon tetrachloride in advised doses does not occupy the premier position which is claimed for it; nor for analogous reasons is beta-naphthol a drug which can be recommended Thymol, and oil of chenopodium of known ascaridol content, used in respective dosage of 4 g and 1 2 c.cm. are safe drugs, the latter being, apparently, the more effective where *A. duodenale* is concerned The choice between the two will mainly be determined by secondary considerations such as palatability and, under mass conditions ease and cost of administration Medicinal iron is of little or no value in the persistent presence of hookworms After their expulsion it will be used as in any other anæmia whose cause has been removed, and there is evidence that arsenic may aid the bone-marrow in the formation of hæmoglobin The solution of the immense and important problem of eradicating ankylostome infestation so far as it depends upon mass treatment can only be effected by the discovery of some drug more specific in its toxicity to hookworms than any now known. The search for such a drug checked step by step by adequate controls is one of the most urgent matters for those who are concerned for the health of several hundreds of millions of the more humble dwellers in the tropics

CLAYTON LANE M D Lond
Lieut.-Colonel Indian Medical Service (ret.)

Special Articles.

THE HEALTH OF LONDON IN 1925.

Dr. F. N K Menzies presents the public health report which has been prepared in collaboration with Sir William Hamer, who was medical officer until the end of 1925 The report opens with a retrospect of public health effort in London since the appointment of the late Sir Shirley Murphy in 1890, and comparison is made with the survey of the same period made by the late Dr James Niven on his retirement from the post of medical officer of health of Manchester. There were many differences to record For example, London at the beginning of the period was already a water-carriage town, while Manchester had to grapple with the difficulties of middens, privies, and the pail system: on the other hand, Manchester had an *unexceptionable* water-supply, while London has had to put the finishing touches to that problem during the last three decades, and has done the work on quite different lines from those of Manchester. In both surveys *great importance is attached to the* removal of filth whether without or within the habitations of the people and both Murphy and Niven laid great stress on good systems of investigation of disease

Improved Environment.

In the present survey details are given to indicate the wonderful improvement in the environment of the Londoner The part played by education and more recently by the medical inspection and treatment of the school-children is emphasised and the following extract gives some idea of the change.

> Any observer who is old enough can recall the appearance of the poorer London children half a century ago when the London School Board was only just beginning to make its influence felt in the days of unregulated child labour, of boy bootblacks and child crossing sweepers: the days of "ragged schools" when bare feet were the rule and frost-bite ophthalmia running ears enlarged glands resulting from skin infestation malnutrition, and deformities were only too common and particularly any medical observer, familiar with the vermin-infested rooms of his midwifery experiences in the slums of London, or with the sight of the skins of children in out-patient departments many of which were peppered with hundreds of flea marks · such an one if he will stand and look at the scholars trooping into school nowadays will realise that the main cause of improved sickness and mortality statistics among the child population in the London of to-day is to be found in the heightened sense of parental responsibility, aroused in a generation of parents who have themselves passed through the schools.

The estimated population of the County of London for 1925 was 4 612 000 The birth-rate was 17·9, the death-rate 11 9, and the infant mortality-rate 68 The death-rate from phthisis was 0 95, from pneumonia 1·04, from bronchitis 0 9, and from cancer 1 44 The rates varied considerably in the 29 boroughs which make up the County of London. Thus excluding the small peculiar population of the City, the highest birth-rates were in Shoreditch 24 5, in Poplar 22 7 and in Bermondsey 22 6 while the lowest were recorded in Westminster 10 7 and in Holborn and Hampstead 12 2. Lewisham had the lowest death-rate, 10 4, while Hampstead, Battersea, and Wandsworth scored a *dead heat* for second place with 10 5 Fulham came next with 10 7 and then Woolwich with 10 8. The highest death-rate was recorded in Chelsea 13 7: Finsbury was next with 13 5 and Kensington Shoreditch, and Southwark were equal third with 13 2 Wandsworth had the lowest infant mortality-rate 54 Woolwich and Hampstead were second with 55 Lewisham had a rate of 56 and Battersea 58 The highest infant mortality-rate occurred in Shoreditch 88 · in Bethnal Green the rate was 81 in Kensington 79, and in Southwark 78 while Stepney, Poplar, and Bermondsey each had a rate of 76 The lowest phthisis rates were found in Hampstead, Lewisham and Paddington 0 59 0 61 and 0 65 respectively, while the highest phthisis-rates were in Finsbury 1 42

Stepney 1 26, Shoreditch 1 19, Bermondsey 1 17, and Woolwich 1·14

The lowest rates for pneumonia were recorded in Wandsworth 0 56, Battersea 0 62, and Hampstead 0 66, while the highest were in Bermondsey 1 59, Poplar 1 55, and Shoreditch 1 37 The lowest rates from cancer occurred in Shoreditch 1 13, Poplar 1 15, Greenwich 1 23, and Stepney 1 24, while the highest were in Chelsea 2,02, Kensington and Westminster each 1 76, and Islington 1 62

Changing Death-rates —Cancer, Small-pox, Influenza

A chart shows the changes in the rates for marriages, births, deaths, and infant mortality since 1840 Up to 1875 the marriage-rate was usually well over the mean figure of 19 and averaged over 20. Since 1875 it has usually been well below 19, but reached the figure of 19 in 1898, rose to 26 in the second year of the war, and was over 22 and 21 respectively in the post-war years of 1920 and 1921 The contour for the birth-rate remained above the mean figure of 30 5 until 1895, since which year there has been a steady decline interrupted by the post-war rise in 1920 The contour line for the death-rate has been below the mean figure of 20 2 since 1895, and has declined steadily since that date except for temporary rises in 1915 and the influenza year of 1918 The infant mortality-rate, unlike the last two, has only been permanently below the mean line since 1905. The average before that date was well over 150 and the decline since that date to the present figure has been very rapid, the chief temporary relapse to a worse state of things being in the hot year of 1911. Another chart shows the contours for groups of diseases and causes of death since 1840 Changes in nomenclature, however, in the classification of causes of death, and in the age and sex constitution of the population make it difficult to draw conclusions from these contours The authors of the report consider that "the view is still defensible that the increase in the mortality from cancer is very largely, at any rate, accounted for by increase in the population at high ages upon which the maximum mortality falls, and by the great improvement in accuracy of certification" They point out that among females the rate of increase has recently fallen They also express surprise that in an age which is reputed to be one of "nerve strain," "brain-fag," and "overpressure," diseases of the nervous system make so little impression upon records of mortality as compared with the far away 'sixties and 'seventies

How wonderfully clear London has kept of small-pox since 1911 is illustrated by a table The periodicity of influenza is discussed at some length and the conclusion is drawn that forecasts of the coming of influenza epidemics two years ahead cannot be made with accuracy The following rule is suggested as a guide, likely to prove more reliable than Dr Brownlee's 33 weeks' periodicity "When an epidemic of influenza reaches a maximum mortality in the half year between the ninth and thirty-fifth weeks (1) it will recur in the succeeding half year, (2) the two epidemics will, as to the time relation of their mortality maxima, tend to balance about the commencement of the thirty-fifth week of the year" A chart is given to illustrate the balancing of influence epidemics round the thirty-fifth week of the year both in the experience of London and Copenhagen A table is also given to illustrate the operation of this rule from 1890 to the present date According to this rule an epidemic should occur about the end of 1926 The epidemiology of typhoid fever in this country and the U S A. is considered, from which it would appear that in both countries the influenza of shell-fish was originally masked by the greater prevalence caused by infected water and infected milk, and that the elimination of drinking water infection in this country took place earlier than in the U S.A. and led to the recognition of shell-fish (and immature ungutted plaice) as a cause of "residual" typhoid at a correspondingly earlier date in Great Britain

The report from the bacteriological laboratory by Dr Graham Forbes illustrates how the examination of the cerebro-spinal fluid may aid the differential diagnosis between encephalitis lethargica, tuberculous and other forms of meningitis, and gross cerebral lesions Dr Forbes has also studied the rôle of the streptococcus in relation to throat infection and the transmission of puerperal fever and scarlet fever, and the remarkable chain of infection linking together cases of puerperal and scarlet fever recorded by Andrewes and Horder is cited

Tuberculosis —Venereal Disease

A history is given of the building up of the Council's tuberculosis scheme In June, 1915, the Council adopted a model for the establishment of tuberculosis care committees by the borough councils Owing to war conditions interim committees had to be appointed to the number of 30 These are being gradually replaced by permanent committees working under the borough councils, and at the present time all the boroughs except four have permanent committees at work In Islington and Bethnal Green the interim committees continue to function; in Lambeth the care work is carried out by the Lady Almoner's department of St Thomas's Hospital, and in Bermondsey the arrangement for this work is still in abeyance The chief duties of these committees are as follow —

(a) The provision of extra nourishment for the family (b) The provision of extra room or extra bed accommodation. (c) The provision of an open-air shelter for erection in the patient's garden (d) The removal of the patient to friends or relatives in the country, or the relief of the family by the boarding out of the children and the finding of suitable work for the patient or other members of the family (e) The care of the children and of the home during the absence of the mother and housewife (f) While avoiding anything in the nature of a sanitary inspection, which is carried out by officers of the borough council, the care committee bring to the notice of the public health authority any obvious defects, sanitary or otherwise, requiring investigation

The present method of selecting cases for residential treatment by clinical medical officers of the staff of the public health department aided by the use of observation beds gives more satisfaction than the methods tried previously The after-history of the patients who received residential treatment during part of 1914 and during 1915, and of insured persons recommended to sanatorium benefit in 1914, was not encouraging The number of cases inquired into was 2987 Of these 47 per cent were early cases, 20 per cent moderately advanced, and 24 per cent far advanced cases Of the early cases 15 per cent, of the moderately advanced 60 1 per cent, and of the far advanced cases 95 5 per cent. are dead

The need for improving conditions at the venereal disease centres which are likely to cause patients to default in attendance continues to receive careful attention The ratio of attendances to venereal cases during 1925 reached the very satisfactory proportion of 36 attendances to each new case, and it is claimed that this figure is not only an advance on previous years but compares favourably with the results obtained in countries where venereal diseases are compulsorily notifiable Another satisfactory feature about the London scheme is the increased use of the facilities for the examination of pathological specimens by medical practitioners There are now 423 practitioners entitled to free supplies of arsenobenzol preparations as compared with 108 at the end of 1917

Puerperal Sepsis

The midwives are supervised by four women medical inspectors, who pay special visits to midwives having cases of a septic nature or persistent high temperature or inflammation of the eyes. There were 316 cases of puerperal fever notified with 78 deaths, but in addition the Registrar-General recorded 26 deaths from puerperal sepsis unnotified during life About 41,000 confinements were conducted by midwives in independent practice, who summoned medical aid in about 17 per cent of their cases. In the practice of midwives there were 422 cases of true ophthalmia neonatorum Impaired vision in both eyes resulted in one case, in one eye in three cases, whilst in six cases the result could not be ascertained owing to removal Sixty-five cases received in-patient treatment at St Margaret's Hospital As regards beds available in London for maternity cases, it is estimated that about 37,000 patients could be accommodated, equal to 43 per cent of the total births Since 1915 the undesirable maternity home has disappeared, whilst the standard of efficiency in other homes has improved

THE POST-GRADUATE CONGRESS AT BUDAPEST

(FROM OUR OWN CORRESPONDENT)

THIS year the Hungarian post-graduate medical congress has been held in the neighbourhood of Lake Balaton Vast tracts of flower forests surround the lake which is so large that it is called the Hungarian Sea, and in the July weather it is an ideal place for a holiday Those who arranged the course of lectures did their best to make the occasion pleasant as well as useful The medical teaching was in the mornings only and the afternoons could be given over to bathing, fishing, and excursions An unprecedented number of doctors came to enjoy this happy mixture of relaxation and learning

The first lecture was delivered by Prof John Bokay, who spoke on his experimental results with the Dick prophylactic inoculations against scarlet fever He had been, he said, one of the first in Europe to try the method, and experience of more than 6000 cases had led to his complete agreement with the Dicks' opinions He saw the closest reaction between the positive result of the cutaneous test and susceptibility towards scarlet fever, and he regarded the Dick test as of great importance from the point of view of prophylaxis Active immunisation by the injection of toxins in gradually increasing doses transformed the reaction in 90 per cent of cases from positive to negative, and it appeared that the immunity thus produced was lasting His experience also corroborated that of American observers who could look back three years and who claimed that the immunity lasted at least for this time The disturbances which might occur during the production of immunity were very mild and were certainly not bad enough to stop the Dick method of inoculation spreading far and wide

Prof Csiky Jozsef, speaking on the pathology and treatment of headache, said that in his opinion the hereditary nature of neurasthenic headaches could not be contested Amongst the causes of headache arising outside the skull the greatest importance should be attached to rheumatism and it was remarkable that so little attention had been paid to this cause in Eastern Europe The treatment was very simple—systematic massage and warm fomentations

Dr Joseph Tornai gave an address on heart disease and pregnancy, in which he said that two or three decades ago the mortality of childbirth associated with heart disease was 30–60 per cent , nowadays it was only 12 per cent at the most Methods of examination, however, as he remarked, are more likely to reveal cardiac disease than they were formerly Besides the strain which pregnancy threw on the heart there was the fear that endocarditis might recur In general it could be said that in heart disease of slight degree, so long as the muscular action was strong the prognosis was fairly good Aortic disease was generally much more serious than mitral The law did not allow the doctor enough freedom of judgment in cases where abortion might be required It was very difficult to say when a patient ought to be advised against marriage but he thought that a girl and her parents should undoubtedly be told the facts

Prof Arthur Hasenfeld in a paper on angina pectoris, pointed out that even yet the ætiology of this disease was obscure From the point of view of prognosis and treatment he deemed it proper to discriminate between angina pectoris on the one hand and aorta syphilitica and aorta nervosa on the other As a prophylactic measure he thought it desirable that people who had contracted syphilis not more than 10 or 12 years before should receive specific treatment regardless of their condition or the results of a Wassermann reaction Prof Hasenfeld expressed himself as opposed to surgical treatment because it excited the patient and might provoke an attack, because it did not affect the fundamental coronary disease, and because pain was the natural warning sent by the heart when it was being given too much work to do

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

The Cost of Private Nursing.

SOME significant facts are emerging in the inquiry now being jointly conducted by the New York State Nurses' Association and the Committee on the Grading of Nursing Schools The practice of assigning one nurse on constant duty to attend one patient is now seen to be an anachronism. It dates from some 50 years ago when women's services were limited in scope, plentiful within their limitations, and consequently inexpensive To-day the reward paid for private nursing of $5 and $7 a day is not sufficient to draw large numbers to the profession and those who graduate as nurses are attracted in increasingly large numbers to salaried positions in institutions The daily pay after all is not large It was found that at a given time, and in the busy season (Feb 21st–28th), only 72 per cent of 1409 private duty nurses were at work , 23 per cent were at home, and 5 per cent were themselves sick in bed The nurse, therefore, is not at work all the year round And when she is at work her wage is found to average only 49 cents an hour, which is the equivalent of the earning capacity of "charwomen, servants, and unskilled labour " Nor is there prospect of advancement There are no grades in private nursing and a graduate of ten years' standing is not supposed to charge any more than a nurse fresh from her training Another count brought against private nursing is that the long hours of duty are unhealthy and demoralising, while the absence of professional occupation for a large part of the time adds to the demoralisation It was found that 80 per cent of the nurses at work were on 12-hour duty and 18 per cent on 24-hour duty Two solutions are indicated : the first is to increase the number of hospitals wherein each nurse can give attention to several patients ; the second solution is one which is already finding expression in the growing activity of the Visiting Nurse Associations Working for these associations the nurse visits several homes each day It happens sometimes that a patient is so seriously ill that one nurse is assigned for constant duty, but this is a service which is very rarely demanded even though it is available There may have been too much readiness to relegate to this system of care only those who cannot afford to pay for a full-time nurse There is no moral or economic justification for any professional worker spending 12 or 24 hours on work that can be done with efficiency in a small part of that time

The Spread of Tularæmia

The Bureau of Biological Survey has recently issued a warning on the prevalence of tularæmia Cases have been reported they say in 22 States, and in the district of Columbia which indicates in their opinion "that the disease probably occurs throughout the United States and that its recognition and occurrence in other States will be only a matter of time, as it was found in nine new States during the past year " The disease may be contracted by contact with the blood or internal organs of infected animals—jack rabbits, snowshoe rabbits, cottontails, and certain species of ground squirrels Many cases have occurred through dressing wild rabbits for the table or cutting them up for fish bait. Infection may also be transferred to human beings through the bite of blood-sucking flies and ticks In human beings the usual symptoms are headaches, chills, bodily pains, vomiting, prostration, and fever, followed by painful swelling and later suppuration of glands It is a disabling disease, incapacitating the patient for weeks or months and at times terminating fatally Occasional cases of conjunctivitis tularensis are also being brought to light. One that occurred early this summer was reported by Dr S W Jackson, of Atlanta, to the Georgia Medical Association A boy of 18 went hunting and killed and cleaned several rabbits Shortly afterwards his left eye became inflamed and assumed the appearance of acute purulent conjunctivitis The usual treatment gave no relief. Smears and cultures were negative, but a blood examination gave positive agglutination for *Bacterium tularense* This was said to be the fifteenth such case on record From the economic point of view tularæmia may prove a blessing It has virtually exterminated swarms of rabbits in some sections of Nevada, Arizona, Utah, and Wyoming, and it is now spreading to millions of destructive ground squirrels The fact that ground squirrels are susceptible reminds one of the anxiety in California recently from the infection of these same animals with plague Perhaps tularæmia may some day be used by health departments as a weapon against the latter more deadly disease

PARIS

(FROM OUR OWN CORRESPONDENTS)

The Coue Institute

NOT long ago the Minister of Labour and Public Health asked the Académie de Médecine to advise him whether the Coué Institute should be recognised as an establishment of public utility A commission of eminent neurologists was appointed to consider the question and reported to the Académie that although the study of metapsychics is of great interest the knowledge available in this domain is still too fragmentary and too controversial to be applied in scientific therapeutics All psychic and metapsychic institutes for treatment which are not wholly under the control of scientific men can have no scientific interest and may well be actually dangerous Accordingly the Académie has decided that it would be inopportune to recommend recognition of the Coué Institute as an establishment of public utility.

The Sale of Skim Milk

On behalf of the Public Health Committee of the Académie de Médecine Dr Jules Renault has lately published a report in which he concludes that skim milk and half-cream milk, whether in the form of condensed milk or powder, ought not to be put on sale unless clearly labelled " Not to be given to young children or to invalids except by the orders of a doctor."

Oriental Sore Contracted in France

As a result of the wars and massacres which have devastated the Near East, large numbers of refugees, most of them Armenians, have landed in France Generally their intention is to go on to the United States, but permits to enter America are refused to invalids A certain number of these refugees have been sufferers from oriental sore and Dr Jeanselme, professor of dermatology at Paris, reports the case of a Russian sailor who contracted the infection from one of them at Marseilles This is the second time that indigenous oriental sore has been noted in France The first case was that of a child who lived during the war in proximity to a company of Kabyles and other North African natives

Vaccinotherapy for Varicose Ulcers

Dr Léon Tixier and Dr P.-R Bize, of Paris, recently communicated a paper to the Société Medicale des Hôpitaux de Paris on the use of intramuscular injections of propidon for chronic ulcers of the legs It is given in increasing doses and the results are described as remarkable There is no doubt, they say, that vaccines have an action in restoring nutrition, acting at first on the ulcer by promoting granulation and reducing suppuration, and later on the peripheral tissues Congestion is reduced and finally disappears and pain is eventually abolished

Foreigners in Marseilles

For a long time past the large number of foreigners in Paris hospitals has been arousing comment The situation appears to be even worse in Marseilles, where in 1925, of 25,248 patients treated some 28 per cent were foreigners. Most of them are Italians, for in certain parts of Italy it is traditional to seek one's fortune in Marseilles It would be a good idea if Italy set up an Italian hospital in Marseilles, or at least gave a grant to the Marseilles hospitals, which find it difficult to carry on under the present strain Most of the other foreigners come from the Near East, and Mr Léon Imbert, who has issued a statement on the situation, holds that it would be suitable for the French Government which has allowed or even encouraged their entry into France, to make some contribution to the expenses which weigh so heavily on the city's budget.

League of Red Cross Societies

Colonel Ernest P Bicknell, chairman of the Central Committee of the American Red Cross, has been elected vice-chairman of the board of governors and will act temporarily as director-general of the League, in place of Sir Claude Hill, who has been appointed Governor of the Isle of Man Sir Claude Hill has been elected honorary director-general in recognition of the wise and valuable guidance which he has given to the League The new administrative commission of the League, appointed by the executive committee, consists of E J. Conill, Cuban Red Cross; H E Geoffray, of the French Red Cross; and Colonel Draudt, of the German Red Cross The board of governors is expected to meet at Paris on May 4th, 1927

French Flour

By decree of the Minister of Agriculture, French flour must now include by-products resulting from the grinding of the grain, these have hitherto been considered waste or have been used for feeding farm animals, or in other ways

Degrais has presented to the Société de Médecine de Paris an analytical study showing the superiority of radium to cryotherapy and other methods in the treatment of angioma Radium, he says, is perfectly safe when employed by competent therapeutists, it is applicable to angiomas of any size and occupying any site, it is painless, it gives perfect cosmetic results, it is applicable at any age, and it never fails

Acetylarsan has been tested for the treatment of yaws by Boisseau in the Congo region It proved efficacious, he says, in 80 cases, representing all ages Two injections of 0 23 g each, corresponding to 0 05 g arsenic, usually sufficed The injections were given 48 hours apart

There are still a few vacancies for the tour of the French spas of the Vosges region, which will be held from August 29th to Sept 8th The fee is 1050 francs, and particulars may be had from Dr Gerst, 94, Boulevard Flandrin, Paris

A post-graduate course on affections of the alimentary canal will be held from Sept 13th to 24th at the Medical Clinic of the Hôtel Dieu, under the direction of Prof Maurice Villaret A three days' study tour to Vichy will follow Further particulars may be had from the Secretary of the Faculté de Médecine in the University of Paris

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Summer Adjournment

PARLIAMENT adjourned on Wednesday, August 4th, for the Summer Recess The date of reassembling was fixed as Tuesday, Nov 9th, but if the stoppage in the coal industry is still proceeding a special sitting of Parliament will be called by Proclamation on August 30th, and monthly thereafter, in order to renew the Regulations under the Emergency Powers Act Among the measures which received the Royal Assent before the adjournment was the Midwives and Maternity Homes Act, 1926

Economy in Hospital and Medical Services

The Select Committee on Estimates have issued a second report to the House of Commons on the possibilities of greater coördination of common services between departments with special reference to the three fighting Services In a section of the report dealing with hospitals and medical services the Committee state —

"One of the recommendations of the Mond-Weir Committee was that a Joint Medical Committee representative of the three fighting Services and the Ministry of Pensions should be set up to secure greater coördination This Committee was appointed in July, 1923, but it has only met eight times in three years The Committee attempted to obtain some standardisation of medical returns for the three fighting Services, but their labours only resulted in the combination of two of the forms used by the Army and Air Force Your Committee were also informed that this Committee had never been able to consider the relative cost of the hospitals maintained by their respective departments because the methods of costing were different They strongly recommend that similar methods of costing should be adopted, and that as far as possible, all forms serving a similar purpose should be standardised

"Although the Mond Weir Committee recommended that greater use should be made of Army mechanical transport by the Navy and Air Force, your Committee regret to find that no steps appear to have been taken in this direction, apart from some experiments in the standardisation of ambulances, which are still going on

"One of the functions of the Joint Medical Committee is to consider the amalgamation of hospitals where possible The amalgamation of the hospitals at Gibraltar and Chatham was carried out in 1922, before the Joint Committee was set up Since that date a scheme for the amalgamation of the three hospitals at Hong-Kong and Kowloon has been prepared, but has been delayed owing to recent events in that part of the world. Schemes for the amalgamation of the naval and military hospitals at Devonport and Plymouth and the two Air Force hospitals at Baghdad are under consideration, and your Committee hope they will be pressed forward Your Committee also recommend that further consideration should be given to the possibility of combining the Army hospitals at Dover and Shorncliffe, of accommodating the wives and children of Army ranks stationed at Chatham in a wing of the Naval Hospital there, and abolishing the small Army hospital still maintained for this purpose Your Committee also consider that the military hospital at Cosham might be absorbed either by Netley or the Naval Hospital at Haslar Under existing circumstances the number of equipped beds maintained at both Netley and Haslar is too large, even allowing for the trooping season, and should be reduced

"The naval and military hospitals at Malta are only some five miles apart, and there is ample vacant accommodation in the naval hospital for Army purposes With modern motor transport such a distance is not insurmountable, and the only other argument against amalgamation advanced by the War Office—namely, that the Admiralty found their hospital too small for their own requirements—is not correct Your Committee consider this question should receive early consideration.

"Your Committee investigated the scale of hospital accommodation provided for the Royal Air Force They noticed that there did not appear to be any general fixed scale, even as a basis of calculation of hospital accommodation to establishment Where accommodation was required it was provided on the basis of the requirements of the year immediately preceding that in which the demand was met This does not appear to the Committee to be a scientific or economical method of laying down a scale of hospital accommodation

"The Ministry of Pensions is unable to utilise military hospitals to any appreciable extent, as they are not situated in large centres of population, where most of the ex-Service men reside

"Your Committee consider, however, that a section of the surgical hospital at Roehampton should be set aside for nurses and the small nurses' hospital at Fernbank closed down "

On the subject of contracts the Committee state that the Air Ministry and Ministry of Pensions have a joint contract with the War Office for the supply of medical stores The Committee see no reason why the Admiralty should stand out of this contract Under the heading of Works Services the Committee state —

"In your Committee's detailed examination of the works under execution by the Royal Air Force it was brought to notice that at Halton a dental hut was being erected at a cost of £1,700 in the middle of the camp They were informed that this was solely to suit the convenience of the establishment although accommodation could have been made available in the hospital which is also being erected in the same camp

Your Committee were also informed that, although the new hospital at Halton will have nearly a hundred fewer beds than the existing one accommodation for the same staff is being provided. The Air Ministry stated that this was due to the fact that the existing hospital is under staffed After comparing the existing staff with that of other hospitals, your Committee do not agree with this statement, and consider the estimate for the new staff to be excessive "

Among the Committee's principal recommendations are the following —

That in the case of the hospital services of the three fighting Services and the Ministry of Pensions, similar methods of costing should be adopted and medical forms standardised to facilitate comparisons

That the question of the amalgamation of the naval and military hospitals at Malta, at Devonport, and Plymouth, the two Air Force hospitals at Baghdad, and the military hospital at Cosham with either Netley or Haslar should receive early consideration

That the War Office civilian hospital at Chatham and the Ministry of Pensions hospital at Fernbank should be closed.

That the estimate of the Air Ministry for the staff of the new hospital at Halton should be reduced.

The Factories Bill.

The text of the Factories (No 2) Bill, which was given a first reading in the House of Commons on Monday, August 2nd, has now been published (Stationery Office. 2*s*) It contains 140 clauses and is a measure which has been under the consideration of the Home Office for a considerable time While it is similar in some respects to the Bill brought in, with the approval of Mr ARTHUR HENDERSON, by the Labour Party, which was discussed in the House of Commons on March 6th, it differs from that measure in important particulars, and should be studied therefore as a new Bill

An official memorandum explaining the extent to which the Bill differs from the existing law was published simultaneously by the Stationery Office (3*d*) This memorandum states that—

The Bill has been introduced in order that the different industries affected may have the opportunity during the autumn and winter of examining the proposals for the amendment of the Factory Acts, which are being put forward by the Government for consideration, of consulting among themselves with a view to arriving at agreements on disputed points, and of submitting any representations they desire to the Government The Bill is the result of a very careful review of the results of the long experience which has been acquired by the department concerned in the administration of the existing Act of 1901, of the inquiries of the numerous committees which have considered different parts and aspects of the wide field of industrial regulation and of experiments and investigations conducted by the industries themselves and by individual manufacturers

The Government do not expect that in a Bill of this kind, affecting many industries of widely varying character and dealing with a wide range of problems arising over the whole field of industrial health, safety, and welfare, there will not be many points in regard to which differences of opinion, possibly wide differences, may prevail in different quarters, but they believe that on the whole the Bill raises the general standard of factory conditions to the level of the better managed and more efficient factories, without placing any undue financial burden on industry, and that the result will be to promote the efficiency of industry as well as the welfare of the workers

The Bill abolishes the distinction which exists in the present law between factories and workshops and between textile and non-textile factories and employs only the one term "factories"; and, except where otherwise expressly provided, the provisions of the Bill apply indifferently to factories of all descriptions. Under the existing Acts, the provisions relating to the sanitary condition of workshops cleanliness, overcrowding, ventilation, and the drainage of floors, are enforced in the first instance by the local sanitary authorities and not by the factory inspectors (as in factories), and the provisions as to sanitary conveniences, both in factories and in workshops, are, in London and in any place where Section 22 of the Public Health Acts (Amendment) Act 1890, is in force, also enforced by the sanitary authorities.

Under the Bill, all the corresponding provisions are enforceable by the factory inspectors, except that in any factory in which mechanical power is not used and which forms part of a dwelling house or shop, or is adjacent to a dwelling house or shop in the same occupation the provisions are to be enforced by the sanitary authority and in the case of any other factory in which mechanical power is not used the Secretary of State if satisfied that the provisions would be satisfactorily enforced by the sanitary authority is to delegate the duty to them

These alterations are of general application The other alterations are alterations of particular provisions and are indicated in a table subjoined to the memorandum in which, however, only alterations of substance are noted

Part I contains general provisions in regard to health. Clauses 2 to 8 relate to cleanliness of factories and workshops, overcrowding, temperature, ventilation and lighting, the drainage of floors, and the provision of sanitary conveniences Freedom from effluvia arising from any drain, sanitary convenience, or nuisance is insisted upon, and all accumulations of dirt and refuse must be removed from the floors and benches of workrooms as well as from the staircases and passages, and among other things it is provided that all inside walls, partitions, and ceilings shall be washed or recoloured every 14 months A factory is to be deemed to be overcrowded if the number of persons employed in any workroom is such that the amount of cubic space allowed for each employee in the case of factories constructed before the passing of the Act is less than 250 cubic feet, or, in the case of any other room, less than 400 cubic feet Measures are to be taken to prevent the escape of injurious or noxious fumes into the air of any workroom, and in every workroom in which a substantial proportion of the work is done sitting the temperature must not, after the first hour during which the work is going on, fall below 60° In regard to all these clauses the Home Secretary may make special orders dealing with the standard of cleanliness, temperature, the provision of fresh air, and so on

Clauses 9, 10, and 11 deal with the power of district councils to enforce certain provisions of Part I, the powers of an inspector as to sanitary defects remediable by the district council, and the powers of the Secretary of State in cases where he is satisfied that there has been default on the part of the district council Under Clause 10 an inspector is empowered to take with him into a factory a medical officer of health, sanitary inspector, or other officer of the district council Clause 12 enables the Home Secretary, after consultation with the Minister of Health, to make provision for the special medical supervision of the workers in any factory, or class or description of factories, where such action appears to be necessary

Part II of the Bill (Clauses 13 to 36) deals with general provisions as to safety Under Part III (Clauses 37 to 41) general welfare provisions are included in regard to the supply of drinking water in factories, first-aid facilities, the provision of seats sufficient to enable all female workers to rest during intervals in their work, the supply of protective clothing against acids and noxious or offensive substances, and the powers of the Home Secretary in regard to welfare orders

Special arrangements for health safety and welfare are also made in Part IV (Clauses 42 to 58) Among the most important of these are the removal of dust or fumes, the prohibition of spitting, the meal rooms of workers in dangerous trades, the prohibition of the use of "white phosphorus" in the manufacture of matches, the prohibition of the employment of female young persons in certain processes, of women and young persons in lifting excessive weights, of women and young persons in certain processes connected with lead manufacture, and of women and young persons in processes involving the use of lead compounds Underground workshops will be prohibited in certain prescribed industries where the inspector for the district certifies the room to be unsuitable for the purpose as regards construction, light, ventilation, or in any other respect Basement bakehouses, except such as were in existence before the passing of the Act, will not be permitted In Clause 55 the Home Secretary is given power to make regulations which appear to him to be reasonably practicable for securing the safety or health of persons employed in industries requiring special measures

The notification and investigation of accidents and industrial diseases are dealt with in Part V (Clauses 59 to 64) Clause 61 provides —

(1) Every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from lead, phosphorus, arsenical or mercurial poisoning, or anthrax, contracted in any factory, shall (unless such a notice has been previously sent) send to the Chief Inspector of Factories at the Home Office, London, a notice stating the name and full postal address of the patient and the disease from which, in the opinion of the medical practitioner, the patient is suffering, and the name and address of the factory in which he is employed or in which the disease was contracted, and shall be entitled in respect of every notice sent in pursuance of this section to a fee of two shillings and sixpence, to be paid as part of the expenses incurred by the Secretary of State in the execution of this Act (2) If any medical practitioner, when required by this section to send a notice, fails forthwith to send the same, he shall be guilty of an offence, and liable to a fine not exceeding 40 shillings (3) Written notice of every case of lead, phosphorus, or arsenical or mercurial poisoning, or anthrax, occurring in a factory shall forthwith be sent by the occupier in the prescribed form and accompanied by the prescribed particulars to the inspector for the district, and the provisions of this Act with respect to the notification of accidents shall apply to any such case in like manner as to any accident as is mentioned in those provisions (4) The Secretary of State may by special order apply the provisions of this section to any other disease contracted in a factory

Clause 62 provides that where a coroner holds an inquest on the body of any person whose death may have been caused by any accident or disease of which notice is required to be given under the Act the coroner shall adjourn the inquest unless an inspector or some person on behalf of the Secretary of State is present to watch the proceedings Among other provisions in the clause there is a subsection which states that where evidence is given at an inquest at which an inspector is not present of any neglect as having caused or contributed to the accident or disease, or of any defect in or about the factory appearing to the coroner or jury to require a remedy, the coroner shall send to the inspector for the district notice in writing of such neglect or defect Clause 63 gives the Home Secretary power to direct a formal investigation of any accident or disease occurring or contracted in a factory and its causes and circumstances

Clause 64 provides —

(1) It shall be the duty of the appointed doctor to investigate and report (*a*) upon cases of death or injury caused by exposure to fumes or other noxious substances, or due to any other special cause specified in instructions of the Secretary of State as requiring investigation, and (*b*) upon any case of death or injury which the inspector for the district in pursuance of any general or special instructions of the Secretary of State may refer to him for that purpose, and (*c*) upon any case of disease of which notice is sent under this Act (2) The appointed doctor, for the purpose of an investigation under this section, shall have the same powers as an inspector, and shall also have power to enter any room in a building to which the person killed, injured, or affected has been removed

Part VI prohibits the employment of children in factories and prescribes the conditions under which women and young persons may be employed Women and young persons may not be employed for more than ten hours in any day, or 48 hours in any week, and their employment shall not begin before 6 A.M. or end later than 8 P.M. on week-days and 2 P.M. on Saturdays Not more than 4½ hours may be worked without an interval of half an hour for a meal Notwithstanding these provisions such persons may work 100 hours overtime in the year, provided such overtime does not exceed six hours in any week. It is further provided that young persons under the age of 16 shall not remain in factory employment after a specified period unless they have been examined by an appointed doctor and certified to be fit for the employment In the section which deals with home work a clause is inserted providing that —

"Where work in respect of which this section applies is carried on for the purpose of or in connexion with the business of a factory in any place which is, in the opinion of the district council, injurious or dangerous to the health of the persons employed therein, the district council may give notice in writing to the occupier of the factory or to any contractor employed by him that the place is so injurious or dangerous, and if the occupier or contractor after the expiration of one week from the receipt of such notice gives out work to be done in that place he shall, unless it is proved to the satisfaction of the Court dealing with the case that the place is not in fact so injurious or dangerous, be guilty of an offence and liable to a fine not exceeding £20"

Clauses 112 and 113 deal with the appointment, duties, and fees of appointed doctors under the Act Clause 112 provides —

(1) The Secretary of State, and, if the Secretary of State so directs, the chief inspector, may appoint a sufficient number of duly qualified medical practitioners to be appointed doctors for any of the purposes of this Act, and may revoke any such appointment Provided that where under this Act the duty of arranging for the medical examination or certification of young persons has been transferred to the local authority for any district, the appointed doctor for those purposes in that district shall be appointed by the local authority (2) A medical practitioner who is the occupier of a factory, or is directly or indirectly interested therein, or in any process or business carried on therein or in a patent connected therewith, shall not be the appointed doctor for that factory (3) The appointed doctor for any factory shall have power at all reasonable times to inspect the general register of that factory (4) The Secretary of State may make rules prescribing the duties of appointed doctors (5) If and so long as there is no appointed doctor for a factory, the Poor-law medical officer for the district in which the factory is situate shall act as the appointed doctor for that factory (6) References in the Workmen's Compensation Act, 1925 to a certifying surgeon shall be construed as references to an appointed doctor appointed by the Secretary of State or chief inspector under this section

Clause 113 provides that the fees paid to doctors shall be such as may be determined by the Home Secretary, and such fees shall in the case of any examination or certificate with respect to the fitness of a young person for employment in a factory and in the case of any examination in pursuance of regulations of a person employed in a factory be paid by the occupier of that factory, and in any other case shall be defrayed as an expense of carrying the Act into effect

By Subsection 3 of Clause 114 it is provided that the medical officer of health of every district council shall—

(*a*) in his annual report to the council report specifically on the administration of and furnish the prescribed particulars with respect to the matters under Part I (Health) and Part VIII (Homework) of the Act which are administered by the district council, and shall send a copy of his annual report or so much of it as deals with those matters to the Secretary of State and (*b*) give written notice to the inspector for the district of any factory coming to his knowledge in which no abstract of the Act is affixed in accordance with the Act

Part XII, which deals with penalties and legal proceedings, provides that the owner or manager of a factory guilty of an offence in contravention of the Act shall be liable to a fine not exceeding £20, and in the case of a continuing offence to a fine not exceeding £5 for each day of its continuance In cases of death or injury it is provided .—

"If any person is killed, or dies, or suffers any bodily injury or injury to health in consequence of the occupier or owner of a factory having neglected to observe any provision of the Act or any order or regulation made in pursuance of the Act, the occupier or owner of the factory shall be guilty of an offence, and, without prejudice to any other penalty, liable to a fine not exceeding £100 and, in the case of a second or subsequent conviction in relation to a factory within two years from the last conviction for the same offence, not less than £10 for each offence, and the whole or any part of the fine may be applied for the benefit of the injured person or his family, or otherwise as the Secretary of State determines "

HOUSE OF COMMONS

MONDAY, AUGUST 2ND

Accident at Orpington Hospital.

On the motion for the third reading of the Consolidated Fund (Appropriation) Bill,

Mr HAYES raised a question in regard to an ex-Service man named William Richardson, who while a patient at the Ministry of Pensions Hospital, Orpington, in 1921, was knocked down and run over by a motor-car within the grounds of the institution. In a question which he had asked the Minister of Pensions on June 17th he suggested that the treatment which the man received in the hospital was not qualified or proper treatment The reply of the Minister, which he regarded as unsatisfactory, was that the Ministry could not accept liability in the matter because the accident occurred at the hospital gates, and was caused by a private motor-lorry which had no connexion whatever with the Ministry The Minister had added that he could find no grounds which in any way supported the suggestion of neglect or improper treatment on the part of the hospital staff During the time that had passed since the question was last raised he had been able to obtain information which not only confirmed the statements he had made, but added to them and he hoped that the Parliamentary Secretary, who he understood would reply on behalf of the Minister, would see the necessity of an inquiry into the matter In July 1921, Richardson was sent to Orpington Hospital for treatment for neuralgia and nerves On Nov 27th he was inside the grounds talking to a military policeman. A motor-car proceeding outside the hospital grounds came into collision with the corner of the wall of the hospital grounds and dashed into the grounds of the hospital When it was six or eight yards inside the grounds it struck Richardson He was seriously injured and taken into the hospital He was not seen by the hospital surgeons in fact he was in his own ward for two or three hours before he was seen by a doctor at all. He was then seen by a physician and not by a surgeon. The physician said that his leg was badly bruised. No further steps were taken, and the man lay for 21 hours in the greatest pain with no further attention. Another 24 hours passed before the leg was X rayed, and it was only on Tuesday afternoon at 1 o clock—the accident had occurred on the Sunday afternoon—that he was visited for the first time by a hospital surgeon The limb was then examined and the surgeon said that it must be put into splints as soon as possible Two hours later, or 51 hours after the accident, the sister in charge of the ward with two orderlies commenced to set the limb without any anæsthetic local or general, and without any qualified assistance It might be that up to that point there was no direct negligence or improper treatment, if it were the practice in any hospital for fractured limbs to be set by persons other than qualified surgeons But he submitted that even if that was the practice, or if a limb could be set by a nurse assisted by orderlies it was a highly improper proceeding that a man who was known by X ray examination to be suffering from a fracture should be treated in that way The man s description of what he went through was something of this kind - ' The sister got two orderlies and three or four patients to hold me down and then started pulling and twisting my limb unmercifully before applying the splints." That statement could be supported by substantial testimony For 17 weeks the man lay in his bed and when the splint was removed the limb was bent and twisted out of all recognition Five days after the splint was removed the man received orders to leave the hospital immediately After protest the man left and on his return home saw his panel doctor who after examining him said that he could do nothing in view of his terrible state The man then went to the Sussex County Hospital for treatment. There he was examined by a surgeon a Dr Turton who was also a doctor or surgeon of the Ministry of Pensions Dr Turton was aghast as was also the surgeon-specialist who collaborated with him They found that little or nothing could be done except by amputation and the limb was subsequently amputated He submitted that the man was inside the hospital grounds when the accident occurred, but even if he were not he would not have been at Orpington at all but for his condition which was directly due to his war service. The responsibility for his presence in that hospital ought to be accepted by the Government.

Lieut-Colonel STANLEY (Parliamentary Secretary to the Ministry of Pensions) said that he realised that Mr. Hayes was raising this matter because of his interest in the man's case, and not from the party point of view, but there were one or two statements in his narrative with which he could not agree. At the time of the accident the man was standing at the gateway of the hospital, and in a thick fog a motor-lorry mounted the pavement and ran into him and knocked him down Clearly the Ministry were not responsible, and attempts were made to trace the responsible party. The lorry itself was actually traced to a firm in the town, but they were able to prove that it was taken out without their consent or knowledge, and they could not be held liable. Mr Hayes had made accusations which he (Colonel Stanley) thought he could hardly believe himself In effect he said that the treatment of this man in the hospital was extremely brutal and that he was not attended to for two or three hours after the accident. He had gone through the whole case carefully and as he read the evidence the man was seen by a doctor at once and was X rayed on the following day It was not until then that it was ascertained that he had broken his leg There were plenty of cases where a fracture was not revealed except as a result of an X ray photograph, and that was the case on this occasion. As soon as the discovery was made that the leg was broken the limb was set. There was no evidence that it was not perfectly properly treated and every possible care taken of the patient. All the time that the man was in the hospital the man made no complaint whatever of his treatment to the head of the hospital When he was discharged five months later the X ray photograph showed that his leg had joined satisfactorily and was in a good condition A court of inquiry which was held as soon as possible to investigate the whole case found that the accident was not the fault of the man nor was it the fault of any official or servant of the Ministry He could not see on what grounds, legal or moral Mr Hayes could claim that this man should be pensioned for his disability If the hon. Member had fresh evidence it would be examined, but unless it was something completely new which could be corroborated he honestly did not see how he could claim that this man should be pensioned for anything else except his war disability

The Bill was read a third time.

TUESDAY, AUGUST 3RD

Rural Housing Bill

Mr NEVILLE CHAMBERLAIN (Minister of Health), in moving the second reading of the Housing (Rural Workers) Bill said there were two features which distinguished the rural housing problem from the urban problem. One was that in the country districts they had a population which was, generally speaking stationary, if not declining and the other was that even in pre-war times the agricultural labourer was never in a position to pay an economic rent for his house. Perhaps to that fact must be ascribed the practical stagnation of house building in rural districts for a great number of years. While the rural housing problem was certainly strictly limited in its extent he did not want to convey the impression that there was no shortage of houses in the country districts As a matter of fact there was a considerable amount of overcrowding in the villages. That overcrowding was partly due to the economic position which had caused a large number of houses to fall into disrepair and become according to modern ideas uninhabitable, though that did not always mean that they were uninhabited It was also partly due to the fact that in many districts there had been an invasion of the country by the town dwellers This had deprived the agricultural workers of the opportunity of getting improved houses

This Bill did not attempt to deal with the question of new building Even the increased subsidy given under the Act of 1924 had not been sufficient to produce any marked activity in the rural districts but it had produced some. Up to the present about 200 local authorities had submitted for the approval of the Minister of Health schemes for providing some 7100 houses The cost, however was very high. The capital value of the Exchequer contribution towards these agricultural houses might be put at about £220 per house and to that they had to add another £80 which was the capital value of the extra subsidy to be provided by the local authority Our country villages contained a great deal that was characteristic of old England in style and material and in the architecture of the cottages It would be something like an act of vandalism if they were to destroy these remainders of an older and more picturesque world in order to replace them with buildings which though they might be sensible, were of a different style and could not be said to harmonise with their surroundings There was, therefore a strong case for the underlying idea of the proposals in this Bill—namely, that they should devote themselves now to an attempt to recondition the old houses in the country and bring them up to modern standards of comfort and of sanitation where they were substantially built It might be asked why the Government proposed to use public money to induce landlords to do what they ought to do themselves without public assistance The answer was that a good many of these landlords were people of small resources who had not the capital necessary to make even such comparatively small alterations as the Government had in mind, and it was not likely without some extra stimulus that they would do in the future what they had not found it possible to do in the past

Proceeding to describe the Bill in detail Mr Chamberlain said that Clause 1 enabled local authorities to submit for the approval of the Ministry of Health schemes for the improvement of houses in the country The second clause defined the power of the local authority to give assistance, and stated that the assistance may either be by way of grant or by way of loan, or by both The assistance is to be given only to houses whose value after they have been altered does not exceed £400 No assistance may be given where the total cost is less than £50 The local authority can refuse to give any assistance at all if they are not satisfied that the house when it is completed is going to be satisfactory for habitation, and a special provision prevents the clause being applied to slums There is a time limit on the operations of the Bill, and applications for assistance must be put in within a period of five years Where the assistance is by way of grant, the grant may be made either by way of lump sum or by way of an annuity It must not exceed two-thirds of the estimated cost of the works, and it is also limited to a maximum of £100 per house It is also subject to various conditions which restrict the rent and limit the class of occupants If any of the conditions are afterwards broken the grant becomes repayable together with compound interest, and is made a first charge on the house Where the assistance is given by way of loan the loan may be made on mortgage up to 90 per cent of the value of the altered house, and advances may be made while the works are in progress up to 50 per cent of the work which has at any time been done

In Clause 3 it was provided that for a period of 20 years the house must not be let to anyone whose income is not comparable with that of an agricultural worker, and furthermore during the same period the rent must not be more than the normal agricultural rent plus 3 per cent upon the amount expended upon the alterations by the owner himself The normal agricultural rent was defined for the purposes of the Bill as the average rent paid during the preceding five years, or if it had not been so let, the rent generally paid in the district by agricultural labourers The owner may rid himself of the conditions which he has undertaken providing that he repays to the local authority the grant which he has received, together with compound interest up to date Clause 4 defined the Government contributions to the expenses of the local authorities The Government contributions must not exceed one-half of the assistance given by the local authority, and as the local authority's assistance was two-thirds of the total cost it would be seen that they contemplated dividing the cost equally, one-third being borne by the Government, one-third by the local authority, and the remainder by the owner himself Clause 5 defined what was to be a local authority for the purpose of the Bill He had come to the conclusion that on the whole the county council was the best authority to undertake the work in the majority of cases, but in cases where the district council ought to be the authority that matter could be adjusted at the discretion of the Minister Clause 6 dealt with the application of the Bill to Scotland

Mr A GREENWOOD, in moving the rejection of the Bill on behalf of the Labour Party, said that the sum which the Minister of Health took away from the insured persons earlier in the year was to go to provide an additional subsidy to the many already enjoyed by the landlords of the countryside The Bill was full of deceptions, and its principle was one with which the Labour Party could not agree

Lieut -Colonel FREMANTLE said there were two things which were particularly piteous to those who had the practical dealing with housing difficulties on the spot The first was that the obvious needs of housing were made a cockpit of politics and were opposed not for housing reasons, but for reasons of political theory pure and simple That was the reason of the opposition to this Bill The second thing was that one saw the old long-tried remedy repeated in different forms again and again brought into the House and put into legislation with the same kind of ideas and ideals, only to prove perfectly useless and worthless in actual practice He wanted to follow out those two remarks from the point of view of an old and tried medical officer of health On paper it was obvious that it would be better to sweep away old and bad housing and to rely on new housing They had tried that method for the past seven years, and they had tried it for years before the war The result had been a few thousand houses built in the country, but that had not touched the real problem, especially the need of the labourer The people could not possibly wait until they could build the necessary number of new houses and close the old ones It had been the one constant endeavour of medical officers of health, especially under the 1909 Act, to pull together the work of all the district officers throughout the county, to summarise their reports, to bring the results before the county council, and to work hard in coöperation with the district authorities in order to see that action was taken where they could not induce the county council itself to use its powers or to take more drastic steps The result of all this procedure officially was very slight, but in actual practice he would not say that it had been so slight This procedure had applied all kinds of pressure and had resulted in education of a most valuable kind It had been found, however, that the district council was too close to the man to be coerced to be able to use powers of coercion properly If they took the larger area—the area of the county—he hoped that they would be able to act more effectively But mere coercion would not solve the problem they must look the economic facts in the face Would they get managers to run estates any more cheaply than the landlords did now? He believed that the present way of running them was the cheapest, but like many other cheap things it did not give altogether satisfactory results He was disappointed that the Opposition had not put forward some constructive proposals calculated to lead to more effective results He was perfectly certain that it would be impossible for the State to take over these bad houses, put them into repair, and manage them They must at the present moment deal with the situation as they found it On the question whether the county council or the district council should be the authority in this case he could conceive of only one way in which the county council could properly manage public health affairs, and that was by the firmest coöperation between the two bodies The district council was in many cases quite unequal to the responsibilities which a much higher standard of public health wished to impose upon them, and it was there that the county council must come in In this Bill the authority was given in the first instance to the county council, but they had power to devolve it in certain cases to the district council He thought that that was probably the right line

The Bill was read a second time by 213 votes to 71

Lead Paint Poisoning

On consideration of the Lead Paint (Protection against Poisoning) Bill, as amended in Standing Committee,

Mr RHYS DAVIES moved a new clause to prohibit the use of lead paint in painting the interior of buildings He said that it was an erroneous deduction that the Government and their supporters had arrived at that Regulations would prevent lead poisoning There was, in fact, no way of dealing with the question except by the total prohibition of the use of white lead in paint This new clause, if carried, would ratify what was termed the Geneva Convention

Mr MONTAGUE seconded

Major HILLS supported the clause The Geneva Convention was signed by the British delegates at Geneva, and he did not wish to see this country fall behind in leadership in industrial reform.

Captain HACKING (Under Secretary for the Home Department) said there was no breach of faith in this matter Sir Montague Barlow, who signed the Geneva Convention, had declared that he voted as he did on the basis of the compromise being a satisfactory one acceptable to all It was clear that the compromise was not acceptable to all A Departmental Committee afterwards reported, and Sir Montague Barlow said that the report seemed to indicate that in view of recent discoveries some of the restrictions embodied in the Draft Convention were no longer of such vital importance as they had been Prohibition for indoor painting and regulation for outdoor painting would be a difficult arrangement to carry out. Regulation as a whole would be much easier to put into operation with success These regulations were only in the nature of an experiment If they failed the Government would not hesitate to bring in another Bill far more drastic with prohibition as its essence He appealed to the employers to coöperate in making the Regulations a success

The new clause was rejected by 198 votes to 74

Dr WATTS moved an amendment to Clause 1 to provide that a medical examination of those engaged in the industry should take place monthly He said that he had had 25 years' experience with regard to lead poisoning and he attached the greatest importance to the method of preventing lead poisoning by medical examination Hon Members had spoken as though lead poisoning were an acute disease and might arise from one exposure to infection He would remind them that it was a chronic disease, which often took months, and even years, to develop Fortunately, it had certain well-marked premonitory symptoms by which it could be easily recognised by medical examination, such as the progressive anæmia and the destruction of the red corpuscles of the blood, which could be easily recognised by the analyst and by the medical examiner, and there was the power under these Regulations to suspend from employment a workman whose health was or appeared likely to be injuriously affected, such as had been found previously, in the case of carbon bisulphide poisoning and mercurial poisoning to be quite sufficient. In order, however, that the examination might be absolutely efficient it was necessary that it should be carried out at certain stated intervals, and that was why he suggested the insertion of the word "monthly."

Captain **HACKING** said he could not accept the amendment, but if his hon. friend would agree to the word "periodical" he would accept that

Dr **WATTS** withdrew his amendment and the word "periodical" was agreed to

Dr. **WATTS** moved an amendment to provide that the medical examination should be made by a certifying factory surgeon. He said that under the Bill the examination could be made by any medical man, but he wished to restrict the department to an examination made by a certifying factory surgeon—that was a surgeon who had had considerable experience in examining and treating cases of lead poisoning

Captain **HACKING** said he could not accept the amendment Whilst almost always the Home Office had the examinations made by certifying factory surgeons, it might be necessary in certain cases that a specially appointed doctor should be substituted. But the great qualifications of the certifying factory surgeon would not be overlooked.

The amendment was negatived

Sir **ROBERT NEWMAN** moved an amendment to Clause 2 to omit the provision excluding women from working in the industry.

Dr **HADEN GUEST** said he hoped the Government would not be led into adopting the reactionary course advocated by Sir R. Newman. There were real physical differences between men and women. The fact that lead poisoning was one of the causes of abortion, and a very important and serious cause, was a sufficient reason in itself to justify a very careful examination of this case, even if it was desired to go back on the proposals of the Bill, which he hoped would not be done. There was a very considerable death-rate from lead poisoning Why should women and children be exposed to the risk of that death?

Captain **HACKING** said the chief reason why he could not accept the amendment was that lead poisoning was a greater danger to women than it was to men. Sir Thomas Oliver, one of the greatest authorities on lead poisoning, said "On the whole females suffer more severely from plumbism than males" Sir Thomas Legge, the Chief Medical Inspector of Factories at the Home Office, said: "Women are more susceptible to poisoning by lead than men." If there was a discrimination in this matter it was a discrimination in the interests of the health of the women.

The amendment was negatived and the Bill was read the third time.

Venereal Disease

The Venereal Disease Act (1917) Amendment Bill, a measure presented by Mr **BASIL PETO**, to permit the sale by chemists of disinfectants for protection against venereal disease, was read a second time and committed to a Standing Committee.

Housing Subsidies

Sir **JOSEPH NALL** asked the Minister of Health if he could make any further statement regarding future policy as to the housing subsidies—Mr **NEVILLE CHAMBERLAIN** replied: It is the general policy of the Government to bring to an end the subsidies under the Acts of 1923 and 1924 as soon as practicable, but it is recognised that this can only be done gradually and with sufficient notice to enable local authorities and those engaged in the building industry to accommodate themselves to the position, in order to avoid breaking the continuity of house production The statutory review under the Act of 1924 falls to be made after Oct 1st next, and I cannot at the present time say what reduction of subsidies, if any, may be made by order under that Act. Any such order, however, must be confirmed by resolution of this House before becoming operative. In the meantime I have decided that houses completed by Oct 1st, 1927, will be eligible for the present rate of subsidy.

Air-craftsman and Tuberculosis.

Mr A R **KENNEDY** asked the Secretary of State for Air whether his attention had been called to the case of Mr F S Smith, ex-leading air-craftsman, No 150,945, Royal Air Force and to the fact that this young man had been discharged from the Air Force suffering from acute tuberculosis after several years' service, including service in the East, and had been refused disability pension, though he had no previous tubercular history, and his medical advisers were of opinion that the disease was directly attributable to his service, and whether he would appoint an appeal tribunal which would ensure a fair consideration of the testimony on both sides in this and similar cases, or would take other steps to remove the sense of injustice caused by an adverse decision arrived at in the absence of medical testimony offered by the applicant.—Sir **SAMUEL HOARE** replied: As the answer is rather long I will, with my hon. friend's permission, circulate it in the official report. As regards the first part of the question, I am advised that the Royal Air Force medical authorities were unable to discover any specific incident of this airman's service in the Royal Air Force which could be regarded as a factor either in the production or in the aggravation of the tuberculosis for which he was invalided. The incidence of this disease amongst Royal Air Force personnel at home and abroad is practically the same and compares favourably with the incidence amongst the civil population of England. There is no evidence to show that general service conditions in Iraq, Egypt, Palestine, or India, are provocative of the onset of tuberculosis. The fact that the disease manifested itself after the airman's entry into the Service does not prove that Service conditions played any part in producing it. As regards the second part of the question, I would refer my hon. friend to the answer given by the First Lord of the Admiralty on May 18th.

Appointments to Senate of London University

Dr. **LITTLE** asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council, upon what advice, if any, he made his selection of persons whom he might recommend for appointment by His Majesty in Council to serve upon the Senate of the University of London. —Major **HENNESSY** replied: My noble friend the Lord President regrets that he is unable to comply with the request of the hon. Member

Fatalities in the Air Force.

Colonel **ENGLAND** asked the Secretary of State for Air if he would give the total number of fatalities to members of the Royal Air Force since Jan. 1st, 1926, indicating the countries in which these fatalities had occurred and the causes, so far as they were known, of the different accidents. —Sir **SAMUEL HOARE** replied: On the assumption that the hon. and gallant Member requires particulars of fatalities in accidents of all kinds, they are as follows, for the period Jan. 1st to July 27th, 1926:—

(*a*) Deaths due to flying accidents, 44; other accidents, 14. total, 58

(*b*) The number of flying accidents was 25, and their causes and the countries in which they occurred were as follows:—

(A.) Home. (B.) India (C.) Iraq (D.) Egypt and Palestine. (E.) Mediterranean.

	A.	B	C	D	E
(1) Error of judgment	8	3	2	4	2
(2) Weather	1	—	—	1	—
(3) Aircraft defect	1	—	—	—	—
(4) Cause not yet known or indeterminable	—	1	1	1	—

(*c*) Particulars as to the 14 non-flying accidents are as follows.—

	A.	B	C	D	E.
(1) Struck by air screen	—	—	—	—	1
(2) Bomb accident	—	1	—	—	—
(3) Motor-car and cycle accidents	12	—	—	—	—

Cost of Poor Relief, Unemployment Relief, and School Feeding

Sir **HARRY BRITTAIN** asked the Chancellor of the Exchequer what money had been spent out of public funds on relief of the poor, relief of unemployment, and school feeding during the past financial year and during the present coal stoppage respectively; and what proportion of this expenditure was attributable to mining areas—Mr R **MCNEILL** (Financial Secretary to the Treasury) replied: The total cost of domiciliary relief for the year 1925–6 was £15 326,700 while the corresponding figure for the eight weeks to June 26th last was £4,025,000 £2,400,700, or 15 7 per cent. of the former amount and £1,352 000, or 33 6 per cent., of the latter amount was incurred in 31 Poor-law unions specially affected by the coal dispute, though the dispute has affected other areas in less degree It is estimated that during the 12 weeks ended July 24th the cost of feeding school-children in the mining areas was about £225,000, or about 25 per cent. in excess of the expenditure on this service for the whole country during the whole year ended March 31st 1926 As regards other expenditure on relief of unemployment I find that an allocation between mining areas and the rest of the country could only be made to a limited extent, and would take some time to work out

Nurses in Prisons

Mr. **PETHICK-LAWRENCE** asked the Home Secretary what number of trained male nurses were employed in His Majesty's prisons, what training and what certificates of efficiency such male nurses held, what was their proportion to the daily average number of prisoners, whether any trained women nurses were employed in His Majesty's prisons for men, and, if so, how many women nurses were so employed and what was their proportion to the daily average number of male prisoners —Captain **HACKING** (Under Secretary for the Home Department) replied 131 male hospital officers, certified efficient by a board of medical officers after training at Parkhurst, are employed in prisons Their proportion to the daily average number of prisoners for 1924–5 is about 1 to 75 Forty-seven of them are on the State Register of Nurses In prisons for men, women nurses are only employed when the medical officer thinks that necessary in special cases

Mr **PETHICK-LAWRENCE** Does that mean that there are no permanent working nurses and that they are only brought in in case of emergency?

Captain **HACKING** Yes, that is what it means

Mr **PETHICK-LAWRENCE** asked the Home Secretary what number of women nurses were employed in H M prisons for women, what training and what certificates of efficiency such nurses held, and what proportion they bore to the daily average of women prisoners —Captain **HACKING** replied Twenty-three registered nurses and 18 hospital officers are employed in women's prisons The registered nurses hold such certificates of training as are required by the General Nursing Council for registration The hospital officers were trained in the larger prison women's hospitals and passed as efficient by the medical officers The proportion of the 41 to the daily average female population for 1924–5 is about 1 to 23

Lancashire Coroner's Error

Colonel **DAY** asked the Attorney-General if his attention had been drawn to the failure of Mr D N Haslewood, a Lancashire coroner, to view the body of George Frederick Margerison, upon whom an inquest was held in accordance with Section 4, subsection (1), of the Coroners Act, 1887, and whether the Lord Chancellor had taken any action in the matter —Sir D **HOGG** replied The Lord Chancellor's attention has been drawn to the case alluded to It appears that by an error the coroner omitted to view the body Proceedings have been taken in the King's Bench Division and a proper inquest has been directed to be held The Lord Chancellor does not propose to take any action in the matter

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Lt-Comdrs to be Surg Comdrs R A W. Ford, C. H M Gimlette, W H A. Sinclair-Loutit, W I Gerrard, R Buddle, and W P Vicary

ROYAL ARMY MEDICAL CORPS

Cols H P W Barrow and D Harvey to be Maj -Gens

J O Priestley is granted a short service commission as a Flying Officer for three years on the active list.

The undermentioned Flying Officers are promoted to the rank of Flight Lt on promotion to the rank of Temp Capt, General List, Army A. Rhodes, H R Peek, and N F Smith.

Flight Lt A. W Comber relinquishes his temporary commission on ceasing to be employed

INDIAN MEDICAL SERVICE.

Temp Lts Gurdat Singh Gill and Lal Singh Anand to be Temp Capts

The King has approved the retirement of Lt-Col E C G Maddock

DEATHS IN THE SERVICES

Lieut-Colonel Rochfort Noel Hunt, D S O, R A.M C, died suddenly on July 26th aged 53 He was educated at the University of Dublin, where he graduated M B, B Ch in 1900 He received his first commission in the Service in November, 1900, became Captain in 1903, Major in 1912, and Lieut.-Colonel on March 2nd, 1923 During the war he commanded the hospital ship *Nevassa* No 135 Field Ambulance No 7 and No 42 Casualty Clearing Station, and No 35 General Hospital, the latter for over four years, and saw service in Egypt and in France Twice mentioned in despatches in 1917, he was awarded the D S O in 1918 and in 1919 he was the recipient of the Medaille des Epidemics (Vermeil, France) On account of heart trouble he was placed on the half-pay list and retired on retired pay on Nov 23rd, 1925

Surgeon-Captain John Charles Groscort Reed, R N, retired, died on August 2nd aged 53 He was appointed surgeon in the Royal Navy in 1896, and four years later was at the taking of the Taku Forts during the war in China in the *Algerine* (China medal and Taku clasp) He was on duty at the time in a temporary hospital between the attacking ships and the forts Later he accompanied the first water party for the relief of Tientsin He was serving at Bermuda when war broke out, and for the last two years of hostilities was afloat as senior medical officer of the battleship *Thunderer* in the Grand Fleet He reached the rank of staff surgeon in 1912 and retired in 1923 after being surgeon-commander in the *Actaeon*, Torpedo School, Sheerness, and in Chatham Naval Barracks

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 31ST, 1926

Notifications—The following cases of infectious disease were notified during the week —Small-pox, 66 (last week 91), scarlet fever, 1245, diphtheria, 728, enteric fever, 65, pneumonia, 376, puerperal fever, 38, cerebro-spinal fever, 6, acute poliomyelitis, 25, encephalitis lethargica, 44, continued fever, 1, dysentery, 6, ophthalmia neonatorum, 123 There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths—In the aggregate of great towns, including London, there were no deaths from small-pox, 4 (0) from enteric fever, 14 (1) from measles, 3 (0) from scarlet fever, 23 (3) from whooping-cough, 21 (4) from diphtheria, 70 (20) from diarrhœa and enteritis under 2 years of age, and 14 (2) from influenza The figures for diarrhœa and enteritis for the last July week show a comparatively small rise on those of the previous week—namely, 68 (12) The figures in parentheses are those for London itself

Typhus Fever in Glasgow—A small outbreak of typhus fever has been reported to the Public Health Department in Glasgow, seven persons (six of them belonging to one family) having been removed to hospital during the first week in August The cases all came from the Govan district and the immediate contacts are being kept under observation at the reception house, where one has since been taken ill with similar symptoms No definite conclusion has yet been reached regarding the source of infection

DANISH HOSPITALS.—Dr Ralph Picken, medical officer of health for Cardiff, has reported to the Corporation upon a recent visit to eight general hospitals in Denmark There are in that country 173 hospitals with four beds per 1000 of the population, and Dr Picken found that the bulk of the accommodation is equal to that of the British voluntary hospitals, and that "the best is better than anything we have." The most marked divergence between the practice of the two countries is in ward accommodation Instead of wards holding 18 or 20 patients, and sometimes more, in Denmark the unit is arranged somewhat on the lines of our own sanatorium or tuberculosis pavilions, a wide corridor at the rear giving access to a series of rooms of various sizes, all of them with windows to the south. Even the smaller hospitals are equipped with new X ray plants, and provision for light treatment, hydro-therapeutics, mechanical treatment, massage, and electro-therapeutics

"Audi alteram partem."

PASTEURISATION OF MILK

To the Editor of THE LANCET.

SIR,—At a time when it is becoming the general rule for dairies to supply their consumers with "pasteurised" instead of raw milk, it is well to consider the advantages and disadvantages of heated as compared with fresh milk. There is a large proportion of people using "pasteurised" milk under the impression that they are receiving the raw product, and the medical officer of health for Poplar is right in holding that when "pasteurised" milk is sold to the public the purchaser should be informed of the fact Forming as it does the basis of diet for infants and young children, milk should be supplied as clean as possible, and at a price which is not prohibitive to the poor, but it should also retain the greatest amount of its natural vitamins and ferments

During "pasteurisation" the lactic-acid, but not the putrefactive or sporulating, bacteria are destroyed, with the result that the milk may go bad without curdling if kept for any length of time Curdling is still looked on as the signal of milk going bad, and the public should be educated not to drink products which are totally unfit for consumption, simply because there is no clot Dr Eric Pritchard,[1] while supporting the general use of "pasteurised" or scalded milk, mentions the fact that at the Infants Hospital the milk supplied to premature or young babies who are not breast-fed is deliberately soured with lactic-acid bacteria, since it is thereby rendered more digestible than "pasteurised" milk Vitamins are partially destroyed on heating, and Prof Plimmer[2] reminds us that heating twice is totally destructive to vitamin C, as in the boiling of already "pasteurised" milk This is especially important in the preparation of many proprietary infants' foods where starch or partially digested starch is present and where it is necessary to make the food with boiling milk and water

Although it is frequently stated that heating to a temperature of 145° F does not impair any of the characteristics of the milk, it can be shown by simple tests that the reductase is destroyed Since enzymes are placed in milk by nature for definite physiological reasons, there is no justification for removing them unless some definite advantage is gained thereby.

In 1883 Richet, working on his patient Marcelin, discovered that whereas fresh cow's milk was digested in three and a half hours, boiled milk required four hours for digestion In this connexion results which I obtained by peptic digestion in vitro are of interest

—	Hours incubated		
	2	18	36
Cold milk	C	M.L, small, broken heavy curd	Nearly digested.
Milk warmed to 50° C =122° F	Well c	M L small compact curd	Not so well digested
Milk boiled and cooled	C l	Flocculent heavy curd	
Cold milk and water in proportion of 7 to 5	C	M L, small, broken heavy curd	Nearly digested.
Milk and water warmed to 50° C =122° F	C	M L, small compact curd	Not so well digested
Milk and water boiled and cooled	C l	Flocculent heavy curd	

C =Curdled l =Lightly M L =Mostly liquid

If pasteurisation is only used for the benefit of the consumer there is much to be said in its favour. But since sporulating bacteria are not destroyed the milk should be consumed within 18–24 hours of pasteurisation, whereas it has been admitted to me by a dairy manager that he keeps milk at his shop for 36 hours before sale, a thing which would be impossible without heating Another manager has told me that "pasteurised" milk goes bad at times in his shop before sale, also pointing to the fact that it is not disposed of quickly enough

At the present time there appears to exist great confusion as to the various grades of milk according to the Ministry of Health regulations, and I know of at least one manager of a multiple company who regularly sells "pasteurised," not Grade A milk, as Grade A and maintains that it is all one and the same product In my opinion, all shops selling any of these graded milks should possess a copy of the regulations affecting their sale, both in their own and in their customers' interests To sum up, it seems doubtful whether the best interests of the public are really being served at the present time by more or less general pasteurisation of milk without educating the consumer on the advantages and disadvantages accruing from the process

I am, Sir, yours faithfully,
THOMAS MCLACHLAN, D C M, A I C.

STATUS LYMPHATICUS.

To the Editor of THE LANCET.

SIR,—An annotation in your issue of June 12th contains comments upon a case of status lymphaticus published by me in the May number of the *Canadian Medical Association Journal* As some criticism is levelled against the diagnosis, perhaps you will allow me to supply additional information regarding the case

Your annotation suggested that the case might have been one of myocardial degeneration and that death was due to this cause Exigencies of space precluded a minute and detailed account of the histological investigation of all the organs The myocardium was, however, carefully examined microscopically and no changes of an inflammatory or degenerative type were found Special attention was paid to the sections stained with Scharlach R and no evidence of fatty degeneration could be seen Another possible omission is suggested by your article—namely, that we were dealing with an early case of acute meningitis and that cultures should have been made from the brain As I had some experience of sudden death from fulminating cerebrospinal meningitis during the war, this was a matter towards which I specially directed my attention at the time of the post-mortem examination It is true that no cultures were made from the brain, but there was not the faintest trace of inflammatory change in the meninges I am interested to know that Prof Glynn has found cases which give positive results bacteriologically when the disease (meningitis) is "practically not demonstrable" otherwise But I take it that there must be something visible to the naked eye As we were on the look out for the condition, and carefully inspected the middle ear, mastoid, ethmoidal and sphenoidal sinuses as well as the meninges I think that possibility may also be eliminated Apart from the generalised lymphoid hyperplasia, the scarring at the lung apices, and the enlarged thyroid, the striking features at the post-mortem examination were the intense venous congestion of the organs associated with a dilated right heart, petechial hæmorrhages, and the pulmonary emphysema The congestion, dilated heart, and the hæmorrhages were all probably associated and were due to the mode of death The emphysema of the lungs was sufficiently striking to suggest an anaphylactic element in the case

I admit the unsatisfactory nature of the diagnosis and our ignorance as to the pathology of the condition

We can only hope that the labours of the Committee of the Pathological Society will result in something more tangible and a better definition as to what exactly is to be understood under the term status lymphaticus.—I am, Sir, yours faithfully,

JAMES MILLER

Queen's University, Kingston, Canada, July 29th, 1926

SURGERY OF ELONGATED PELVIC COLON.

To the Editor of THE LANCET

SIR,—Mr E. G Slesinger's paper on this subject in your last issue will create widespread interest. The elongated pelvic colon is a serious cause of stasis In its extreme form the elongation is enormous and is an insuperable obstacle to successful treatment Its surgical removal offers great attraction, and Mr. Slesinger's cases prove that success may follow resection of redundant bowel with end-to-end union But success is not invariable I have records of a good many X ray observations after resection (for cancer, diverticulitis, &c). Union is perfect, but function remains imperfect and does not improve with time. There is a break in peristaltic continuity, due to division of Auerbach's plexus The peristaltic waves do not bridge the gap Fæces accumulate at the union until enough has been thrust through to start an independent wave in the distal section. Mr Slesinger gets over this difficulty by giving paraffin and by enemata if paraffin fails My own conviction is that a case severe enough to warrant surgery is best treated by complete colectomy, for then the distal section receives no solid matter and cannot become obstructed. I am well aware that colectomy is a serious responsibility. If Mr Slesinger's less drastic operation can be made to succeed, it will be a boon indeed.—I am, Sir, yours faithfully.

ALFRED C JORDAN

Upper Wimpole street, W , August 7th, 1926

THE DEFINITION OF DRUNKENNESS

To the Editor of THE LANCET

SIR,—As a police surgeon it is my unpleasant duty to examine persons accused of drunkenness, and like Dr. N. I Spriggs I have been unable to find a satisfactory definition of the condition

The committee appointed by the British Medical Association to consider the tests for drunkenness will doubtless formulate a concise and comprehensive definition Meanwhile I define drunkenness as an obvious impairment of the functions of the nervous system due to alcohol Alcohol disturbs first the higher intellectual faculties, then the motor centres If a suspected person sways or staggers in his gait, slurs his speech, or makes clumsy and ill-adjusted movements when he sits down, handles his cigarette case or other familiar things, I assume that there is a disturbance in equilibrium in the coordination of the muscles This loss of control of the motor mechanism, when due to alcohol, indicates a more pronounced impairment of the higher functions of the brain and is definite evidence of drunkenness And as arrests for drunkenness are rarely made unless the suspected person smells of alcohol, and has the muscular incoordination and disorderly behaviour peculiar to alcohol, very few sober people are taken into custody.

When there are no motor symptoms, and one has to rely on mental changes only, drunkenness is not always easy to detect, for the medical man does not know the normal condition of the drinker, and has no standard of comparison The mental derangement which attends the slighter forms of intoxication is usually revealed by the self-satisfied behaviour of the affected person The drunken man is pleased with himself and his conduct; he has a diminished sense of his responsibility, and if a motorist makes light of any accident that may have occasioned his arrest Although accused of drunkenness he loses his caution, and states the kind and number of drinks he has had He breaks the convention in a way he would not do when sober , he wears his hat indoors, sits when he should stand, smokes without permission, and is familiar and facetious He is talkative and argumentative, and may wander off to irrelevant subjects He loses control of his emotions and becomes maudlin or too genial

When these mental symptoms are combined with muscular incoordination there is no doubt about the diagnosis. When, however, the mental symptoms are present without motor derangement the suspected person is often said to be under the influence of drink but not drunk. This phrase is misleading and is better avoided. It led to the acquittal of Dr Spriggs's "drunken" motorist and has been equally serviceable to many another drunken man It is probable that half the adult population is under the influence of alcohol at some time in the day, but not every person so influenced is drunk. If, however, the mental effects of alcohol can be readily detected, not only is the subject under the influence of drink, but according to my definition he is drunk He may be steady on his legs and correct in his speech, but his sense of responsibility, his judgment, his estimation of distances, and his caution are all gravely impaired and replaced by a reckless sense of well-being and disregard of danger which make him a greater menace to society than any person who is drunk and incapable

I am, Sir, yours faithfully.

Birmingham, August 9th, 1926 G. A WILKES.

DEFENCE OF ASSISTANTS AND LOCUM TENENTS.

To the Editor of THE LANCET

SIR,—I am instructed by the Council of the Medical and Dental Defence Union of Scotland Limited to bring before the notice of your readers the fact that this Union, which enrols medical and dental practitioners in any part of Great Britain and Northern Ireland, has always accepted responsibility for the acts of their member's assistant or locum tenent If, therefore, a claim is made, or an action raised against a member of this Union in respect of a negligent (or alleged negligent) act of his assistant or locum tenent, the Union will defend the case The Union's indemnity insurance scheme, under which members are protected in the event of an action against them being unsuccessfully defended, also covers the member, not only against his own negligence, but that of his assistant or locum tenent

I am, Sir, yours faithfully,

W FINDLAY,

Secretary and Treasurer to the Union.

155, St Vincent street, Glasgow, C 2, August 3rd, 1926

CERTIFICATION OF INJURY UNDER THE WORKMEN'S COMPENSATION ACT

To the Editor of THE LANCET.

SIR,—I see from your report of the Representative Meeting (THE LANCET, July 31st, p 229) that the British Medical Association is considering a form of certificate to be issued to injured employees at the request of the employer, who acts on the instructions of the insurance company This question has interested me for some years, and I made inquiries about it from two solicitors, one barrister, and one representative of an insurance company who was calling on me in reference to insurance work The first three said the employer had no right to ask for a certificate from the employee , the insurance man said, as nearly as I can recall his words, "I am giving the show away, but we have no power to ask for a certificate" The employer has the right to have the employee examined at his own expense I believe there is nothing in the Acts requiring the employee to go to a medical man If my contention is correct why should any concession be made to the companies? The only reason given at the meeting was that some medical men charge sixpence each for these certificates —I am, Sir, yours faithfully,

F DE COVERLY VEALF

Market Lavington August 5th 1926

CERTIFICATION OF INCAPACITY FOR WORK

To the Editor of THE LANCET.

SIR,—Has it ever occurred to those responsible for certain clauses of the National Health Insurance Act that they have put into the hands of panel patients a weapon which is used alarmingly and which is now producing the new memorandum of the Ministry of Health? In these days of competition the practitioner has to keep a practice together, to lose a practice is easy, and one method of doing so which is extremely efficacious is to question too frequently the patient's demand for a certificate Patients know only too well they can change their panel doctor daily if they desire, and they do not hesitate to tell you and do so The remedy is to control this liberty, and when the panel doctor is thus safeguarded, and his sense of security heightened, probably his moral integrity will improve Doubtless this has escaped observation, but a return to the six months or even three months limit for changing the doctor will be worthy of trial, it can at least do no harm —I am, Sir, yours faithfully,

August 9th, 1926 PANEL DOCTOR

To the Editor of THE LANCET.

SIR,—As far as this area is concerned, there has certainly been an increase of the number of references to the regional medical officer, though as there are a number of pits working my impression is that the increase is not as large as elsewhere. The circumstances are also different, as in one coalfield most of the miners have chosen a particular approved society which has an amount of sickness greatly in excess of the normal, as much as 99 per cent of what is provided for under the Acts (so the secretary told me some time ago), as compared with 75 or 80 per cent for other societies In order to save themselves from bankruptcy and knowing their members well, the local officials of this society are down at once on their younger members on the sick funds whom they suspect in a time of strike The result is a tremendous rise in the number of references, and from my own experience of such cases it is evident to me that many men fall back on sick pay as a convenient method of getting money in an emergency

This undoubtedly has thrown on to doctors practising in such areas a very thankless and onerous work, and all the more so owing to the number of doctors who have no conscience about giving certificates These doctors are largely "black-leg" doctors who in previous years have been got in by the miners Though in great minority they are sufficiently numerous to make the position of the remaining doctors very difficult This has become more so since the time when a patient could change his doctor at any time I have come across cases where the doctor who has been in attendance has signed off a man because he was convinced of his ability to work, and by so doing has lost not merely his patient but a whole family In one case 35 insured persons left one doctor because he signed off one man In this case a deputation from the miners' lodge waited on the doctor and demanded that he should alter his certificate which he refused to do I know of the case of one insured person who getting a final certificate from one doctor, went the same day to another doctor who gave a continuation certificate and got the insured person transferred to his list

My sympathies are increasingly aroused for those doctors who try to do their duty under such circumstances In a big town a doctor is not exposed to such risks or temptations, but in a mining village where the doctor's whole livelihood depends on one set of people it is very different.

I am, Sir, yours faithfully,

August 10th, 1926 GIDEON GRAY.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to each member of the medical profession. If the form has not been received, a duplicate will be sent on request We shall be grateful for the return of the forms by an early post We are, Sir, yours faithfully,

J. AND A. CHURCHILL

7, Great Marlborough-street London, W. 1,

ROYAL COLLEGE OF PHYSICIANS OF LONDON The College will close for the long vacation on Saturday, August 14th, and reopen on Monday, Sept 20th.

UNIVERSITY OF LONDON—*Thomas Smythe Hughes Fund*—A grant of £20 has been made to Dr K N G Bailey towards the cost of an investigation of certain strains of the *Bacillus coli*

Negotiations are proceeding with the trustees of the Bedford Estate regarding the acquisition of a part of the Bloomsbury site, and at its meeting on July 21st the Senate passed a resolution —

That the Coördination and Developments Committee be authorised to take immediate steps to secure for the University the longest possible continuance of the temporary occupation of the Malet-street site, on the understanding that the Senate will be prepared to continue negotiations for the acquisition of so much of the Bloomsbury site as is practicable having regard to the urgent importance of increased accommodation for the University at South Kensington

HOSPITAL PENSIONS SCHEME—The Provisional Council of the King Edward's Hospital Fund for London is inviting hospitals to submit any points of detail in connexion with the scheme on which they may desire information or decisions These questions should, if possible, be sent before Sept 25th, and in any event not later than Nov 1st Hospitals wishing to notify their readiness to participate and to send representatives to the next meeting of the Provisional Council, should write to the Provisional Executive Committee not later than Nov 15th.

SELLING GAME FOR HOSPITALS—The Mackintosh of Mackintosh, President of the Northern Infirmary at Inverness, has addressed a circular letter to shooting tenants in the Highlands asking them to help the collection of £100,000 for the extension of the infirmary by selling some of their grouse and other game for its benefit The game is to be sold to a specified firm of dealers in London at ordinary market prices

JOINT TUBERCULOSIS COUNCIL—A post-graduate course on non-pulmonary tuberculosis will be held at Heatherwood Hospital, Ascot, Berks, from Sept 23rd to 25th next The lecturer will be Dr J G Johnstone, the medical superintendent, and a fee of 1½ guineas will be charged The course has been approved by the Minister of Health as ranking for grant Applications and inquiries should be sent to the hon secretary, Joint Tuberculosis Council, Post-graduate Courses, at 19, Brunswick-square, Camberwell, London, S E 5

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION—Starting on August 16th the Queen's Hospital for Children will hold an all-day course on the medical and surgical aspects of children's diseases The course will last a fortnight and the entire practice of the hospital will be thrown open. A simple luncheon and tea will be provided A brush-up course in medicine, surgery, and the specialties will be given at the Queen Mary's Hospital, Stratford, from August 23rd to Sept 4th Instruc- tion will be available throughout each day, and the hospital is equipped with a new pathological department and maternity wards Continuous weekly courses in obstetrics are given at the City of London Maternity Hospital, and the Fellowship can arrange practical courses in anæsthetics for graduates From Sept 6th for four weeks special lecture- demonstrations on diseases of the eye will be held at the Central London Ophthalmic Hospital, where the clinical practice of the hospital will also be available From Sept 6th eight bi-weekly lecture-demonstrations in psycho- logical medicine will be given by Dr Porter Phillips and the medical staff of the Bethlem Royal Hospital From Sept 13th to 25th the Infants Hospital will hold a course under the direction of Dr Eric Pritchard for medical officers of welfare centres and others From Sept 20th to Oct 1st the Westminster Hospital will provide an intensive course in medicine, surgery, and the specialties, and the National Orthopædic Hospital staff will hold an all-day course from Sept 20th to Oct 2nd Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, W 1

International Physiological Congress.—The twelfth meeting of the Congress was opened on August 3rd at Stockholm by Prof. J E Johansson. Sir Frederick Gowland Hopkins gave an address on the Mechanism of Biological Oxidations

Chelmsford Poor-law Infirmary.—This new infirmary was opened recently It contains accommodation for 120 beds, chiefly in four main wards, each of which has attached a large sun-room facing south. The flat roofs can be used for open-air treatment

Newcastle-upon-Tyne Royal Infirmary.—The annual report of the house committee states that 13,281 patients were treated during 1925, the highest number on record. During the year 2000 extra beds were put up to relieve the pressure, and 17,496 accident cases were dealt with

Princess Mary and Northern Hospitals—Princess Mary on August 6th opened an extension of Ripon Cottage Hospital as a memorial to King Edward and Queen Alexandra. The extension includes a Princess Mary Ward for children given by Miss Cross Next month Her Royal Highness will open a large addition to Stockton and Thornaby Hospital which will increase the accommodation from 72 to 135 beds

Cancer Research in the University of Sheffield—At a meeting of the Yorkshire Council of the British Empire Cancer Campaign held on July 26th it was agreed that the University of Sheffield should receive £10,000 over a period of five years for carrying out work on dietetics under the direction of Prof. E Mellanby and with the approval of the Director of Cancer Research. Accommodation and full equipment will be provided out of this sum. Over £100,000 has now been subscribed to the Yorkshire Council of the British Empire Cancer Campaign, but £30,000 more is asked for

The Future of Voluntary Hospitals—On August 6th the Minister of Health opened in Glasgow a new hospital for the treatment of ear, throat and nose diseases In his speech Mr Chamberlain said that until the 13,000 additional beds which are needed in the voluntary hospitals of England, Wales, and Scotland are provided and the maintenance costs assured, the voluntary system would not have entirely consolidated its position When he came to recast the Poor-law he hoped to devise a scheme which would enable the municipal hospitals, which contain 30,000 beds, to work in close coöperation with the voluntary institutions He thought that ' we might do worse than aim at the establishment of some central health authority in every district," which would decide what hospital accommodation was necessary and make sure that it was forthcoming.

Donations and Bequests—The late Mr Charles Edward Craston, of Oldham-street, Manchester who left a fortune of £79,462, left a large residue to the Manchester Royal Infirmary and Dispensary, St. Mary's Hospitals, Manchester, the Royal Manchester Children's Hospital, Ancoats Hospital and Dispensary, and the Manchester Royal Eye Hospital, the Hospital for Consumption and Diseases of the Throat, Manchester—By the will of the late Mr Thomas Harrison Evans of Walsall, the testator left £1000 each to the Walsall and District Hospital, the Walsall Victoria Nursing Institution, the Wolverhampton and Midland Counties Eye Infirmary, Dr Barnardo s Homes, and the Queen's Hospital Birmingham—The late Mr T Bailey, J P, of Hessle, Hull among other bequests left on his wife s decease a certain large capital sum as to £10,000 to the Hull Royal Infirmary, £1500 to the Hull Royal Infirmary for the Withernsea Convalescent Home, £1000 to the Hull Royal Infirmary for the Withernsea Sanatorium for Consumptives £10,000 to the Victoria Hospital for Sick Children Hull, £2000 each to the Hull and Sculcoates Dispensary, the Hull Jubilee District Nursing Association, £1000 to the South Hunslet Nursing Home, Hessle, and certain sums to the Hull Royal Infirmary And the residue of his property as to one-fifth (together with any lapsed shares) to the Hull Royal Infirmary one-tenth each to the Victoria Hospital for Sick Children, Hull and the Hull Blind Institution.—Mr Edward John Dent, of Belsay Northumberland left £1000 to the Royal Victoria Infirmary, Newcastle-on Tyne to endow a cot—Miss Violet Wills of Haytor has given £1000 towards the proposed hospital for Devon and Cornwall Crippled Children—The Hon Louisa Elizabeth Kinnaird left £2000 to the Instruction Society of the Zenana and Medical Mission.—Major Francis Barrow Pearce, C M G of Shanklin Isle of Wight who left £21,974 after several bequests gave the residue of his estate to be divided between the Westminster Hospital, St George s Hospital, and St Thomas s Hospital

Lancashire's Fight against Tuberculosis—The Rufford Pulmonary Hospital, near Ormskirk. was opened on August 5th. It was formerly Rufford Hall and was bought by the county in 1919. The total cost of the hospital and estate was nearly £32,000, towards which about £8000 was contributed by the Lancashire Insurance Committee and a substantial sum by the Ministry of Health There is accommodation for 50 patients Since the end of the war the tuberculosis death-rate for Lancashire has fallen from 107 per 100,000 of the population to 67 in 1925 Rufford makes another link in the county council's chain of four pulmonary hospitals and three sanatoriums The county tuberculosis death-rate is now lower than the general average for England and Wales

The late Dr W. Bruce Bell—For many years a well-known and busy practitioner in the High Broughton district of Manchester, Dr William Bruce Bell died at Paignton in Devon on August 4th. Born at Falkirk in 1871, he was educated at Blairlodge School and at the University of Edinburgh, where he graduated in medicine with distinction in 1893 He held medical and surgical appointments at the Edinburgh Royal Infirmary and was house surgeon at the Edinburgh Hospital for Sick Children. Settling in practice at Manchester, Dr. Bell became medical officer to the post office and medical referee to several assurance companies In 1907 he was admitted to the Fellowship of the Royal College of Surgeons of Edinburgh. The state of his health prevented active service during the war, but he did excellent work as medical officer in charge of the Grecian-street Branch of the Second Western General Hospital. He was a keen politician, and at the time of his death chairman of the North Salford Conservative Association. He leaves a widow, a son, and a daughter

MALARIAL PARASITES AND METHYLENE-BLUE

Methylene-blue was used in the treatment of malaria as long ago as the 'nineties of last century and various investigations into its value have been made Writing in The Lancet (1920, i 1334), D G Marshall recorded his experience of its use at the Edinburgh War Hospital, Bangour, where over 3000 cases of malaria were treated, and disagreed with the view that it has toxic properties "In acute malarial attacks," he said, "it was found that though in many cases favourable results were obtained, the efficacy of methylene-blue in cutting short attacks was distinctly inferior to quinine On the other hand, it frequently proved a valuable remedy in preventing relapses, especially in cases where quinine, administered by the mouth or by intramuscular or intravenous injections, had signally failed." He came to the conclusion that "in methylene-blue we possess a remedy of great value, and that provided a pure supply is obtainable, it may be freely used without fear of 'toxic' symptoms resulting"

An investigation of the effects of methylene-blue on the parasites themselves has lately been made by Dr Apostolescu, as is recorded by our Bucharest Correspondent, who gives the following account of his work.

"Dr Apostolescu administers methylene-blue in three daily doses of 25 cg each to patients in whose blood tertian parasites have been found The first changes observed begin at the end of the second day and affect only the full-grown forms, the smaller, younger forms remain unchanged The adult organism shows diminished movement and breaking up of the protoplasm into lumpy rounded bodies, which lie in the blood-cell apart from one another, or are connected by minute bands of protoplasm and pigment granules The protoplasm of these lumps is shrunken. The nucleus of the parasite is generally found near the periphery of the blood cell, and on staining with carmine violet its appearance is granular. Among the sporulation forms Apostolescu found besides normal sporozoites, others which were not fully formed The pigment is gathered in patches, and these are irregularly distributed The chief points noted in the action of methylene blue on the tertian forms were destruction of the protoplasm and absence of alteration of the chromatin In the parasite of æstivo-autumnal fever no changes were observed In the crescent forms there was shrinking and granulation of the protoplasm He noticed a more equal staining of the whole parasite than normal and that the pigment granules appear coarser and are grouped in an irregular mass which projects from the surface of the shrunken protoplasm The destructive process of the protoplasm of malarial crescents goes on until there is nothing of the parasite left except the pigment.'

THE PATHOLOGICAL SERVICE OF THE GENERAL HOSPITAL

A PATHOLOGICAL department is now recognised as essential to every hospital but there is still uncertainty about the part it should play in the hospital economy. In different places and under different systems there are wide variations in its organisation and in its relation to other branches of medical practice. In a paper read before the annual meeting of the British Hospitals Association on June 25th Dr S C Dyke discussed the means of securing efficient pathological service in the smaller general hospitals and offered suggestions on the coördination of such a service with insurance and private practice in its area The following summarises some of the views he expressed.

The Hospital Pathologist and Outside Practice

After referring to the value of accurate records, which he described as for the most part sadly lacking in the smaller hospitals, Dr Dyke turned to the pathologist's work outside the hospital itself. The work done for the wards, he said, must be the justification for the existence of the laboratory The laboratory will, however, be open to the receipt of work from the outside and this private work should form a source of income to pathologist and hospital alike. The most satisfactory arrangement seems to be that under which the pathologist is paid a salary or retaining fee from the hospital, is allowed to use the laboratory for his own work, and receives a proportion of the fees coming in for services rendered.

The work sent from outside will fall into two classes—that done for private practitioners and that done for public bodies It is very desirable that the pathological department of a general hospital should be a centre for the exchange of views among medical men and a place to which they may take the problems occurring in their practices for such light as the pathologist can throw upon them. Sporadic visits from medical men may interfere with the smooth running of the laboratory, but they are to be regarded as an essential part of the daily round. The laboratory, in fact, must be looked upon as instituted not only for the benefit of the hospital, but also for that of the practitioners of the surrounding district. The work done for public bodies will be largely on contract and will consist of such items as the examination of throat swabs for diphtheria, of sputum for tubercle bacilli, and so forth. Such work will usually be catered for at special rates It is advisable that the laboratory should not be swamped with work of this sort, but a certain amount of it is very desirable as bringing a steady and certain income into the department Most local authorities arrange for the performance of examinations of this sort free of charge to the practitioners, the cost being a charge upon the rates

Important as this work is however, it should not be allowed to overshadow the other activities of the laboratory A tendency has arisen, and is unfortunately growing, to regard a pathological laboratory as a sort of slot machine which, in return for a specimen be it a swab or a bottle of sputum or of urine, will supply a diagnosis and even a cure in the shape of a jorum of vaccine Such is not its function. In many cases the pathologist faced with a specimen can have no idea in what direction the investigation should proceed without information from the clinician or without himself seeing the patient Coöperation between pathologist and medical staff is necessary for the efficient working of the practice of the hospital and the rule applies exactly to the relations of the pathologist to the practitioners served by the hospital and its laboratory.

In many instances local authorities have provided their own laboratories for the performance of such pathological work as is paid for out of the rates So long as this step results in saving the ratepayers' money it cannot be regarded as other than admirable, but in one recent experiment the result was to deprive the laboratories of the general hospitals in the county of a large part of their income, to burden the county rates with an expenditure for which there was no justification, and to give a further fillip to the unfortunate tendency to expect the State to pay for everything In the majority of instances it should be said, no such clash has arisen between the laboratories of the general hospitals and those supported out of the rates, for county and municipal laboratories usually confine their activities to the sphere of public health If local authorities generally were to throw open their laboratories to all the practitioners in their area for the free performance of investigations of all kinds, in the long run it would not bring about any improvement in medical practice On the contrary, such a step would distract the specialists in the pathology of public health from their own field and would ultimately have the inevitable effect of rendering the ground work of medicine a State department. It seems inadvisable that any branch of medicine—and in particular such an important one as pathology—should become bureaucratised.

Panel Practice.

There is every indication that in the near future the laboratories of the general hospitals should be able greatly to extend their sphere of usefulness. It is one of the anomalies of the panel system that, although from its inception it has given every facility for the treatment of disease in so far as treatment can be carried out by bottles of medicine, it has provided no facilities for diagnosis. For 16 years now the panel practitioner has been left to make his diagnoses as best he can, but one of the steps recommended by the recent Royal Commission upon the National Health insurance system was that provision should be made for pathological investigations for panel patients The need for such provision is obvious and offers the sole excuse for such a step on the part of a county council as offering to perform such investigations in its own laboratory To offer to perform them free of charge is, however, to take liberties with the ratepayers' money For the performance of such investigations for panel patients ample funds exist in the reserves of the approved societies, while private patients have always been in the habit of paying according to their means. As pointed out above, it is further desirable that pathological investigations concerning the individual rather than the national health should be made in the laboratory of the general hospital to which the patient will himself come for treatment when he is ill.

In some areas provision has been made in advance of any alterations in the panel system for the investigation of panel cases in the laboratories attached to the general hospitals Thus the Chester Royal Infirmary undertakes pathological investigations for panel patients and their dependents at something below the rates charged to private patients and Wolverhampton and Staffordshire General Hospital has recently inaugurated a similar scheme in association with the Wolverhampton panel committee. Under this scheme certain examinations will be performed at half rates for panel patients and their dependents.

The justification for such a step exists in the fact that in the vast majority of cases no examination would be made were full fees charged Some such arrangements will undoubtedly become general when the recommendations of the recent Royal Commission are given effect This being so, there are two points to which all interested in the welfare of the voluntary hospitals should give their attention. These are —

1. That reasonable fees shall be paid to the departments for the work done

2 That all such investigations shall be carried out in the laboratory attached to the general hospital serving the district in which the patient resides.

These two points are mutually dependent. In the absence of some regulations concerning them it is inevitable that a large number of the investigations under the scheme will be done at cut rates in commercial laboratories having no connexion with the hospital to which the patient will go when in need of hospital treatment This appears undesirable from the patient's point of view

The first point might form the basis for consultations between the British Hospital Association and the Ministry of Health. Hospital pathologists have no representative body which might draw up a scale of fees for pathological work but in conjunction with the secretaries of their hospitals who are also concerned they would be willing to give their assistance in drafting such a schedule for submission to the Ministry The suggestion that all pathological investigations be carried out in the laboratory of the general hospital serving the district in which the patient resides is of equal or greater importance Such an arrangement would be of enormous benefit to the voluntary hospitals throughout the country, in that it would assist them in the equipment and maintenance of efficient pathological departments. Apart from the question of adequate payment there is no measure more calculated to improve the status of pathology and by so doing to raise the standard of medicine generally throughout this country

---

THE mother of the late Sir Ernest Shackleton and her daughters are in straitened circumstances, and as Sir Ernest Shackleton's father was a medical man, it is right to commend to the notice of our readers a fund which has been started on behalf of the widow and family. Contributions should be sent to Mr Percival [illegible] Parliament-street, S.W.

PUBLIC HEALTH IN BECHUANALAND

THIS Protectorate is a country of British South Africa, in the centre of the vast tableland stretching north to the Zambesi, and the population at the census of 1921 was 152,983, of whom 1743 were whites, 52 Indians, 1003 coloured, and 150,185 natives Mr C L O'B Dutton, Government Secretary, in his report for 1924 states that the health of the territory was very good throughout the year The relative incidence of disease remains the same, malaria, syphilis, and bronchial affections prevailing in the order given The high place occupied by catarrhal diseases of the chest cannot, however, be assigned to them as separate entities They are often the concurrent or remote manifestations of malarial infection, which thus, as always, maintains its great preponderance There were no acute, severe, or widespread outbreaks of fever or epidemic disease except eight cases (one European) of cerebro-spinal meningitis which occurred at different centres, of which seven terminated fatally During the year the rainfall was the heaviest within the last two decades This would presume, prima facie, an increase in malarial incidence But it is not necessarily in seasons of heaviest rainfall that fever and its attendant complications and sequelæ take their heaviest toll—it is in seasons of drought and scarcity with their consequent lowered standards of living and powers of resistance With the heavier rainfall there is a corresponding improvement in grazing conditions and an abundance of staple agricultural products

There is evidence, in the steady increase of applications for antisyphilitic remedies at the various centres throughout the territory, of a growing eagerness to benefit by the provision of free treatment of venereal disease At Molepolole alone, where a Government dispenser has been in charge for the past nine months, 500 cases have been treated From Mochudi, where in the absence of a Government dispensary the issuing of medicines is entrusted to the representatives of the Dutch Reformed Mission, the reports are equally favourable Although no statistics have been submitted, the nurse in charge of the Mission dispensary reports that the demand for free treatment is very great, a fact confirmed by the Gaberones medical officer during his monthly visits At Kanye 464 cases have been treated A fresh extension of the work is contemplated in visits by the district surgeon of Kanye to Moshupa and Manyana In the northern part of the territory, owing to changes and interruptions throughout the medical service, exact statistics are not available But the reports from various reliable sources are all encouraging, and, with the gradual completion and stabilising of the medical service, and increased resources for accumulating stocks of the necessary novo-arsenical preparations, the possibilities in this particular field are very great and to a large extent realisable

The death of one of the medical officers during the year led to a certain amount of disorganisation The consequent changes and service requirements have been met by a temporary arrangement, the permanent readjustment to be postponed pending the selection of a suitable whole-time officer An important step in the extension of the medical service has been the appointment of a medical officer to N'gamiland Discussions have taken place as to the possibility of making a beginning with the building of small modern hospitals at one or two of the principal centres, and, financial circumstances permitting, provision will be made on this behalf in the next estimates The daily average of patients treated at Gaberones during the year was 7 78, of whom 0 01 were Europeans, making the total number of treatments 2346

The prevalence of plague, bubonic and pneumonic, in certain portions of the Union contiguous to the territory, and particularly at De Aar and Kimberley, which are situated on the direct line of railway from the south, prompted the administration to take certain precautionary measures, both within and without the territory For some time past the most effective trap procurable both for rats and mice has been in use in all public offices, stores, and buildings, and monthly returns of captures are rendered *to*, and collated by, the principal medical officer The European officials and other residents of the territory have also been made alive to the need for destroying *rodents* wherever seen. Particulars as to the life-history of the flea and the several methods of destroying the insect have been disseminated amongst *the inhabitants*, European and native, with a plain intimation that fleas were the carriers to human beings of plague germs from plague-infected rodents and other furred animals, and an intensive campaign of destruction was encouraged The P M.O has under consideration a scheme for preparing and assembling in advance all the essential elements of an organisation which would be capable of dealing with plague in territory should *an outbreak* suddenly occur In this respect he is fortunate in having the assistance temporarily of Dr P Targett Adams, late medical officer of health for the *Orange* Free State, whose experience of plague in the Union is almost unrivalled

HAY FEVER, TRUE AND FALSE

THIS year hay fever seems to have been discussed more *than usual in the press* and in lay circles, but it would be rash to draw the conclusion that it has been more prevalent Some twenty years ago it was customary for practitioners to dismiss this distressing *complaint as* mere neurosis, of which any worthy citizen ought to be rather ashamed Nowadays, hay fever is as respectable as a broken leg, and just as any acute fever is liable to be *called influenza, doctors* are tempted to diagnose any rhinorrhœa as hay fever We may point out that for this year true hay fever has ended, for it only lasts so long as the pollen cloud lasts over England In the south this period extends almost exactly from May 20th to July 15th—a little earlier or later according to the weather, and certainly a little later this year But it varies less than might be imagined, since it depends more on length of daylight than on temperature Symptoms do not coincide exactly with these dates for two reasons (1) conditions are described as hay fever without adequate reason, (2) concurrent illness may supervene and blur the outlines of true hay fever Anyone called on to treat "hay fever" after the middle of July should first consider whether pollen ever had anything to do with the symptoms and if so what other sensitisation is now keeping them going, infected *throat*, teeth, and tonsils—and possibly infections elsewhere—may be incriminated Other possibilities must be borne in mind, including substances in food or in atmospheric dust—e g, horse-dung to those who are horse sensitive In the treatment of pseudo hay fever, specific therapy can be expected to do little or nothing *unless a more accurate diagnosis* can be made There remain for consideration shock tactics, suggestion, and ointments or washes containing mild local anæsthetics or adrenalin—*according to the taste* or idiosyncrasies of the practitioner

AN IMPROVED SPOON THE "*CACHON*"

THE accident of a spoon slipping into a plate of soup or other liquid or semi-liquid food is annoying, and to prevent such contretemps "cachon" table ware has been devised by Messrs Joseph Gilbert and Sons, of Sun Works, Bissell street, Birmingham At the handle end of the spoon or fork, and underneath it, a slight projection, technically called a nib, is made at right angles to the plane of the article in such a manner as to prevent it slipping beyond the edge of the plate or vessel in or on which *it may be resting* The "nib" is in no way conspicuous, does not affect the balance or handling of the article, and does not detract from any beauty of design *that it may possess* Table spoons or forks, salad servers, butter knives, dessert spoons or forks, and tea spoons are made with the non slipping device in Era Silver, *Nuva Plate* Gilbert Plate, and in other materials for table ware manufactured by the firm

A HASTY GENERALISATION

THE following reached us unvouched for by signature, but it is worth printing as showing how the estimate of one angry man, probably in connexion with one piece of tactlessness, may produce sweeping denunciations, damaging *to the medical profession* —

> *The Infirmaries and Hospitals*
>
> All over the country these institutions are getting into the control of cliques of unscrupulous guinea *snatching doctors*
>
> Doctors get put upon the staffs of hospitals, through various forms of influence, nepotism, freemasonry, and the like, seldom or never through any special merit
>
> By or through their connexion with a hospital these men are enabled to pretend to be specialists, and to charge three guineas a visit or even a consultation There is no such thing among them as a specialist in surgery, medicine, or midwifery, indeed, many of these frauds have been common panel doctors and they would remain such but for their hospital appointment
>
> People who can visit these humbugs and pay *them* three guineas can get a bed without any waiting, often next day
>
> Poor people have to wait months and mostly go into the workhouse wards Mostly they go unrelieved.

These hasty generalisations, though sincere, are mischievous The *development* of local consulting, based upon local esteem, is exactly the outcome of panel practice which is most to be desired Patients seen *privately* are often found to need prompt hospital treatment, and no general indictments of hospital administration or professional conduct can be founded upon this situation No doubt abuses occur, but certainly not to the extent that warrants an attack of the above sort, *which* we publish in order to deny its accuracy as a series of generalisations *Of the* particular episode which led up to the communication we know nothing

Hunterian Oration

ON THE

HÆMORRHAGIC DIATHESIS: ANGIO-STAXIS.*

By H LETHEBY TIDY, M.D. Oxf,
F R C P. Lond,
PHYSICIAN, ROYAL NORTHERN HOSPITAL, AND ASSISTANT PHYSICIAN, ST. THOMAS'S HOSPITAL.

The existence of a hæmorrhagic diathesis is generally accepted but the term is little used in medical literature Patients come under observation suffering from various types of hæmorrhage and from forms of anæmia for which it is frequently difficult to find a definite diagnosis Often such cases are finally entitled "primary purpura" or simply "severe anæmia" Such well-recognised entities as leukæmia, acholuric jaundice, hæmophilia, and congenital syphilis are not referred to here, nor are cases where the symptoms are secondary to some other cause such as sepsis We shall be considering the shadowy group of primary purpuras and hæmorrhages from the mucous membranes Purpura is the predominant manifestation but the clinical variations are innumerable

The types of primary purpura usually described in text-books in the past are (1) purpura simplex, (2) purpura rheumatica, (3) Henoch's purpura, and (4) purpura hæmorrhagica

Single cases appear in the literature with very varied blood pictures under titles such as "acute purpura," "recurrent hæmaturia and severe anæmia," "purpura hæmorrhagica," "chronic purpura hæmorrhagica," "chronic purpura hæmorrhagica without skin lesions," "hereditary purpura," and many others, and also in recent literature as "essential thrombopenia," "aleukia," and various titles relating to changes in the platelets and the effects of splenectomy The question is how far these are to be regarded as separate conditions or as various grades and stages of the same entity.

CLINICAL ASPECT

Two clinical features which have attracted much attention in the past are joint pains and abdominal pains The classification of primary purpura given above largely depends on these features, but little attention is paid to them in recent writings Joint pains are a feature of nearly every case of purpura of more than the slightest severity, and hence do not justify the separation of a special group Henoch's purpura, however will for the present be left out of consideration as it appears probable that escape of fluid from the vessels, apart from the solid constituents, is a special feature of this type, which thus justifies the term, "anaphylactoid" purpura, used by the French

No two accounts agree as to the characteristics of purpura hæmorrhagica On such points as the size of the spleen, the number of the white cells and changes in the bone-marrow the accounts are vague and usually incomplete The clinical points apparently relied upon for diagnosis are the severity of the symptoms and the occurrence of hæmorrhage from the mucous membranes, especially the gums It is remarkable how many writers ascribe great importance to hæmorrhage from the gums It is clear however, that the diagnosis usually rests clinically on the severity of the hæmorrhages

Now it is possible to trace, not only in different individuals, but sometimes even at various periods in the same individual every grade between purpura simplex and purpura hæmorrhagica There are families in which one member exhibits slight chronic purpura alone, another member hæmorrhages which may be confined, for example, to hæmaturia or epistaxis, while yet another member may exhibit the severer types [1] Cases also occur where an individual may at one time pass through severe and dangerous attacks and then for long periods exhibit mild grades of purpura or perhaps epistaxis or hæmaturia alone. Several cases were recorded by Osler,[2] but, in fact, in varying degrees they are by no means uncommon in practice In such cases no dividing line can be drawn between different types and groups, and the manifestations are evidently those of the same entity occurring in varying grades of severity .

Recently a separate group of purpura has been described under the title of "Essential Thrombopenia" or Thrombocytopenia.' Frank,[3] who is responsible for this, definitely stated that he considered the entity as identical with what has been described as purpura hæmorrhagica in the past It appears from a study of his cases (and still more from those of other authorities described under this title) that he includes grades far less severe than would have been classified clinically as purpura hæmorrhagica The justification of such an entity, therefore, cannot rest on the clinical manifestations and must depend on features in the blood, which will be referred to subsequently This is a question of special importance, since it is widely stated not only that splenectomy is indicated in this group, but that it should be performed in no other type The study of cases published recently by authors other than Frank under this title with successful results from splenectomy show that they have drifted, and in my opinion correctly so, still further from cases which would have been diagnosed in the past as purpura hæmorrhagica and it is doubtful whether some of them would have been accepted originally by Frank as his entity on clinical or even on hæmatological grounds The cases now being regarded as purpura hæmorrhagica or essential thrombopenia are mainly those that in the past would have been regarded as severer or more chronic forms of purpura, but not of the severity which used to justify the term purpura hæmorrhagica; many would have been placed in the group of purpura rheumatica. Clinically there is no definition which will differentiate them, they do not correspond to a separate type but only to a certain grade of severity As evidence of the unity of the various groups, a recent statement of Kaznelson[4] may be quoted to which Bruce Williamson[5] has referred, "that the effect of surgical treatment in this case was to transform purpura hæmorrhagica into purpura simplex."

It is evident that no clinical distinction except degree of severity can be drawn between these various forms with the exception, perhaps, of anaphylactoid purpura.

EFFECT OF CAPILLARY HÆMORRHAGES ON THE BLOOD AND HÆMOPOIETIC TISSUES

The Bone-marrow

It may be accepted in general, without entering into details, that the marrow supplies red cells, polymorphonuclear leucocytes, and platelets [6] The response of the marrow to the escape and loss of blood from the vessels and to the resulting demand for replacement will vary with the severity the frequency of the occurrence, and the acuteness or chronicity of the hæmorrhages The effect on the bone-marrow may be summarised as follows —

1 *Sudden Severe Demand*—The marrow and hæmopoietic tissues though normal at the time may be unable to supply from its reserves sufficient cells to maintain life, other changes have not time to occur Thus in the extreme types recorded as "acute purpura hæmorrhagica or "purpura fulminans, the marrow at autopsy rarely shows any definite changes It may be noted that the colour and apparent extent of the red marrow present in all these conditions is influenced by (1) the actual amount of red marrow tissue present (2) the degree of anæmia and consequent

---

* Based on the annual Hunterian oration (1926) of the Hunterian Society

5373

pallor, and (3) hæmorrhages into the bone-marrow itself which may closely simulate red marrow tissue and give the appearance of an increased area and activity

2. *Milder Grades of Hæmorrhages.*—The marrow may be able to cope with these losses sufficiently for life to continue The output may be insufficient completely to replace the losses, and various degrees of anæmia and of deficiency of platelets may be directly due to this cause There is little direct evidence of the state of the bone-marrow in such stages, but apparently it may be in varying grades of slight hyperplasia or anaplasia.

3 *Repeated Hæmorrhages* —These may continue to be just a little more than the marrow can replace, until finally chronic exhaustion occurs and the marrow becomes aplastic As repeated severe demands would lead to rapid failure, as in Group 1, it would be expected that in this group the hæmorrhages cannot be very marked, at least until the terminal stages, and clinical records are consistent with this The patient is indeed more anæmic than purpuric, a condition often observed in childhood With aplasia or with the slighter condition of anaplasia there will be diminution even of the normal supplies of cells, and this at a time when the demand is greater than normal

Effects on the Spleen.

The functions of the spleen as regards the blood fall under three main headings 1. Action as a reservoir 2 Destruction of defective cellular and formed constituents 3 Formation of lymphoid cells

(1) The action of the spleen as a reservoir for the blood has been emphasised by Barcroft and his co-workers[7] It is evident that a normal spleen during life holds a considerable amount of blood in reserve

(2) It may be accepted that the spleen will destroy cells which are below a certain standard, either from senility or defective production Unfortunately we have no means of judging when red cells are effete In the hæmorrhagic conditions it may be expected that the marrow will produce a higher proportion of defective red cells when working under unusual demands In any case the spleen will be destroying red cells which could partially function and in the circumstances be of advantage to the organism This undoubtedly occurs in acholuric jaundice and is the reason for the benefit of splenectomy The position with regard to platelets will be similar to that of the red cells

Whether the spleen enlarges or not will depend on the absolute number of effete or defective cells to be dealt with and not on their proportion to the total. When the marrow is aplastic and the red cells constantly number, say, 1,000,000 per c mm , the total work for the spleen may be less than normal, and there is no reason why the spleen should enlarge ; in fact, it is rarely palpable in these cases In acute severe forms of hæmorrhage the action of the spleen in dealing with the débris of cells from the hæmorrhages may be a factor in producing enlargement of a spodogenous nature ; in these cases the spleen may or may not be palpable, but usually becomes so if a very severe condition lasts for a few days It has often been observed in severe cases that the spleen becomes palpable as the condition improves and the number of circulating cells increases[8,9] The spleen, therefore, is not usually palpably enlarged in the mild or in acute conditions, or when the number of red cells is very low It is most often palpable in cases of moderate severity When palpable in severe cases the enlargement may have occurred previously It has to be considerably enlarged before it becomes palpable In this group of conditions it is rare for the size to exceed one or two finger-breadths below the costal margin Thus the enlargement is very variable and the question whether it is palpable in a given case is a matter of comparatively little importance A marked enlargement is, however, of importance as indicating that the case probably does not belong to the hæmorrhagic diathesis

(3) It is clear that in this condition, as in others, the production of lymphocytes suffers less than does that of other cells Little else can be said as to lymphocytes and the lymphopoietic tissues, since unfortunately we know practically nothing as to the life, death, or functions of these cells

Changes in the Blood Cells and Hæmoglobin

These will depend on many factors, such as the condition of the bone-marrow, the chronicity of the hæmorrhages, and their severity at the period of observation With sudden severe purpura and hæmorrhages there is necessarily a very rapid fall in the number of red cells and an equivalent or greater fall in the percentage of hæmoglobin, the reserves being exhausted and the amount of replacement being small There is usually also a fall in white cells, especially polymorphonuclears, no doubt because the marrow is more greatly affected than the lymphoid tissue This results in a leucopenia with a relative lymphocytosis The percentage of lymphocytes may rise to 60 or 70, or higher.

In the chronic forms, characterised usually and almost necessarily by the less severity or even slightness of the obvious hæmorrhagic manifestations, there is usually a persistent marked reduction of the number of red blood cells With this there is often a leucopenia with relative lymphocytosis, which may be ascribed to anaplasia or aplasia of the bone-marrow ; in such cases the tendency to improvement between exacerbations and under treatment is certainly less than in those with a leucocytosis

The effects of the hæmorrhagic diathesis may give a blood count suggesting or even identical with lymphoid leukæmia Cases have been recorded in the literature in which the polynuclear cells have been entirely absent, and the diagnosis of lymphoid leukæmia[10] would certainly have been made had not the patient recovered If hæmorrhages are also present, there does not appear to be any method by which the two conditions can necessarily be distinguished, either clinically, pathologically, or hæmatologically Probably some of the cases diagnosed as acute lymphoid leukæmia but without any glandular enlargement are really of this nature

In the cases of moderate severity the number of red cells in a quiescent period may be normal or nearly normal, or it may be reduced in varying extents, and this reduction is naturally increased during any exacerbation The leucocytes may be, and in moderate chronic cases frequently are, definitely increased with a high percentage of polynuclear cells , this is evidence of activity of the bone-marrow and no case with such a white cell count need be despaired of. Since the changes in the number and percentage of the various cells must depend on so many factors, it is not surprising to find that there is no constancy in the changes Practically every combination may occur of (*a*) changes in the number of red cells, with (*b*) leucopenia or leucocytosis, and (*c*) increased percentage of lymphocytes or polynuclears Rapid variations may also occur in the number of the cells The hæmorrhagic diathesis accounts for many of the cases which appear in the literature with blood counts which do not fit into any of the recognised entities These are especially common among children and leads to the attempt to make many classifications on different bases and to many disputed diagnoses

The changes in the percentage of hæmoglobin follow in general the changes in the number of red cells There is the usual tendency of hæmoglobin to form more slowly than the red cells, a reduced colour-index resulting, but this is less constant than in most anæmias, and the colour-index may be nearly normal. The morphological changes in the cells are only those which would be expected to accompany the changes already referred to In the cases associated with marked anæmia there may be anisocytosis and poikilocytosis and, less commonly, such changes as polychromatophilia and punctate basophilia, but these may be completely absent and the red cells appear normal even in severe cases Normoblasts in small numbers are not uncommonly found but megaloblasts are very rare and practically confined to cases in children With leucocytosis a few myelocytes or doubtful myelocytes may be present. There is no alteration in the fragility of the red cells.

Platelets

The normal number of platelets in the blood may be taken as 200,000 to 300,000 per c.mm The estimation of the number is subject to a large margin of error, and only large variations can be definitely recognised It is, however, apparent that the number of circulating platelets is very susceptible to factors influencing them and it may vary with great rapidity.

It may be accepted that the function of the platelets is concerned with preventing the escape of blood from the vessels, and that in fulfilling this function platelets are withdrawn from and lost to the circulating blood Hence in hæmorrhagic conditions the number of platelets is influenced first by the group of factors already discussed, which affect the red and white cells, including the chronic and immediate extent of the hæmorrhages, and the condition of the bone-marrow and spleen; and secondly, by an additional factor, the withdrawal or consumption of platelets resulting from their attempts to check the hæmorrhages It has long been known that there is a marked decrease or even complete absence of platelets in cases of hæmorrhage of the type of purpura hæmorrhagica It must, however, be emphasised that a reduction may be present in any case with purpura and hæmorrhages, whatever the origin may be It may almost be said that they must of necessity be diminished in the circulating blood when capillary hæmorrhages are severe Hayem pointed out that reduction in the number of platelets occurred even in secondary purpura but the statement that reduction is confined to purpura hæmorrhagica has been copied from one book to another. They are also reduced to the neighbourhood of zero when the marrow is aplastic, whatever may be the cause of the change.

In less severe forms of the hæmorrhagic diathesis the number of platelets shows changes of the same nature as the red cells, though always with a greater response to the occurrence of purpura and hæmorrhages and the greater tendency both to rapid variation and to diminution The number may be within normal limits in the quiescent periods of moderate cases This may be so even in conjunction with some grade of anæmia. The number is more frequently below normal and may be at any point, depending no doubt on the factors mentioned above It is common to see the figure in the neighbourhood of 100 000 per c mm.

In cases of the hæmorrhagic diathesis, the number of platelets may thus be anywhere between normal and zero, and no definite line can be drawn at any point which will divide the cases into separate groups or entities Nor will a count of platelets serve to distinguish "primary" from "secondary" purpuras Neither clinically nor from a study of the blood-cells and platelets can any distinction be drawn except in severity between the various manifestations of the hæmorrhagic diathesis

COAGULATION TIME AND CERTAIN OTHER PHENOMENA.

1 *Coagulation Time* —When tested by recent methods the coagulation time in the hæmorrhagic diathesis is within normal limits By Wright's method it is often difficult to say at what point the blood has clotted. For a considerable time it may be in a sticky state when it can just be expelled from the tubes Coagulation may commence within normal limits but not proceed normally and clotting may not be completed for a considerable time This is probably the explanation of many cases in which prolonged coagulation times have been recorded in the past, the diagnosis between hæmophilia and the hæmorrhagic diathesis may thus be obscured. It is remarkable that this is especially observable in German literature where the distinction between the two conditions usually does not appear to have been clearly recognised until recently. The phenomenon differs entirely from hæmophilia, in which the onset of coagulation is delayed but clotting proceeds normally when it commences The modern methods of estimating the coagulation time will clearly distinguish hæmophilia

2. *Prolongation of Bleeding Time*—When the hæmorrhagic diathesis is active the bleeding from a prick, if the blood is dabbed off at half-minute intervals continues for many minutes or even long periods, instead of ceasing in the usual normal time of one to three minutes This prolongation of the bleeding time may be very marked, but in quiescent periods it is usually absent. It is an interesting feature in the hæmorrhagic diathesis but bleeding time is a very variable manifestation and may be prolonged in other conditions, especially with anæmia and too much importance should not be attached to it

3. *Capillary Resistance Test*—Partial constriction of the arm by a band may produce a crop of petechiæ. This is an interesting phenomenon, but like the preceding test, it is usually absent in quiescent periods.

4. *Failure of Clot Retraction*—When blood from a case of the hæmorrhagic diathesis in the active state is allowed to clot in a tube, the clot which forms often does not retract and express the serum normally. This phenomenon is not uncommon in many other conditions and is familiar to every worker in serum.

It may be said of the above tests that they add little definite information except in the valuable distinction from hæmophilia

CAUSE OF THE HÆMORRHAGIC DIATHESIS.

The essential manifestation of the hæmorrhagic diathesis is the escape of blood through the walls of the capillary and small blood-vessels The cause of this is at present in doubt; it must lie initially in some abnormality either of the blood or of the wall of the blood-vessels.

Attention has lately been especially directed to the influence of the platelets, and it is generally accepted that they have some action in preventing capillary hæmorrhages Duke[11] ascribed this to their property of adhering rapidly in masses to the wall of a blood-vessel at any point where the endothelium is injured or unduly permeable the initial lesion of the hæmorrhagic diathesis thus being placed in the vessel wall Frank[3] believes that the platelets are primarily concerned with coagulation, and that the hæmorrhages are due to defects of clotting when the circulating platelets are reduced in number. He has described a syndrome of "essential thrombopenia," which he considers to be a true disease, a "sharply circumscribed clinical entity," and in which the reduction of platelets is the primary event None of the characteristics given distinguishes "essential thrombopenia" from other forms of purpura otherwise than as a grade of severity, and the view that a separate disease can be carved out of the primary purpuras on these grounds should be abandoned. There is definite evidence that reduction in the number of circulating platelets is not the essential cause of the hæmorrhages. Brill and Rosenthal[12] removed the spleen from a patient with hæmorrhages in whom the blood showed a great reduction in the number of platelets Subsequent to the operation the platelets fell to 1000 per c mm., but the hæmorrhages had not returned. Other observers have had similar results Bedson[13] has carried out extensive experimental investigations on platelets in animals and he has produced a serum which will reduce the platelets to zero without the occurrence of any hæmorrhages. It appears clear that variations in the number of the circulating platelets are not the initial factor in the primary purpuras.

It does not appear possible that changes in the blood-cells are the cause Every variation may be observed and there is no constant change Neither leucocytosis nor extreme leucopenia[6] are necessarily associated with hæmorrhages No abnormalities have been distinguished in the blood which are comparable to acholuric jaundice or hæmophilia.

It has been suggested that the spleen may act in some manner on the blood rendering passage through the vessel walls abnormally easy. This explanation is negatived by the fact that hæmorrhages may recur after splenectomy

By the process of exclusion we are led to the view that an abnormal permeability of the blood-vessels is the essential factor, but there is little direct evidence Bedson[14] watched under the microscope the mesenteric vessels of an animal rendered hæmorrhagic experimentally by injections of certain sera He states that "the majority of the hæmorrhages appear to form by an exaggerated form of diapedesis" On microscopic examination of the tissues "the endothelium appears swollen and œdematous, the cells standing off the vessel walls" Bedson also produced hæmorrhages in animals by the use of two different injections, the first designed to injure the vessel endothelium, and the second producing a reduction in the number of platelets Neither of these caused hæmorrhages when employed alone As reduction of platelets alone does not result in hæmorrhages, it would appear that the essential factor is injury to the vessel endothelium.

The evidence brings us back to the view expressed by Duke many years ago that the essential factor in primary purpura is an abnormal permeability of the endothelium of the small vessels The function of the platelets is to adhere to such permeable sites and prevent the escape of blood In so doing the platelets are withdrawn from the circulation The greater the reduction in their numbers, the greater will be the possibility of blood escaping from unprotected points Any condition, such as aplasia of the marrow which causes a diminution of platelets, places the body in a susceptible state ready for hæmorrhages to occur, and increases the tendency if already present

Such a view brings the primary purpuras into a line with conditions characterised only by escape of the fluid portions of blood The term "angio-staxis" may be suggested to include the primary purpuras and the various manifestations of the hæmorrhagic diathesis

The Effects of Splenectomy

Kaznelson[15] first performed splenectomy in a case of purpura hæmorrhagica in 1915 Since then numerous cases have been reported

Whipple[16] has reviewed over 80 cases. In very acute cases the mortality has been very high, but excluding these unsuitable conditions the immediate mortality does not exceed 10 per cent No doubt some fatal cases have not been recorded, but the results of series suggest that with greater familiarity with the operation the mortality will tend to fall The beneficial results in the surviving cases are undoubted

Bedson[17] has investigated in animals the effect of splenectomy on the production of experimental purpura His results show that. 1. The number of platelets rises after the operation and returns in a few weeks to its previous figure 2 Increased protection against a hæmorrhage-producing serum is present while the number of platelets is increased The protection is only comparative and is lost when the number returns to normal 3 After a few weeks the animal has returned to the statu quo ante, other tissues having taken on the functions of the spleen

In the hæmorrhagic diathesis in the human being the important effects of splenectomy may be summarised as follows. 1. The number of platelets rises almost immediately After a varying lapse of time it may fall again to the previous level 2 The hæmorrhages diminish or cease immediately after the operation 3 Recurrences may take place, but rarely to a severe degree.

The result of splenectomy may be partly explained by reference to acholuric jaundice, in which it is agreed that the marrow is primarily producing a high proportion of red cells which are not perfect, but which are able to carry out their functions to a useful degree. Owing to their imperfection they are destroyed in large numbers by the spleen, and the body consequently benefits by splenectomy The condition in the hæmorrhagic diathesis is not quite the same, but the removal of the spleen will diminish the destruction of cells and platelets and permanently remove one source of drain on the marrow The immediate effect on the hæmorrhages may be ascribed to the flooding of the circulation with platelets either from reserves or from stimulation of the marrow in the same manner as the well-recognised leucocytosis which follows splenectomy Splenectomy is not a "cure," but it is the best method of treatment available.

Indications for Splenectomy.

Reasons have been given for considering that all cases of the hæmorrhagic diathesis belong to one group, and hence the question whether splenectomy is indicated or not arises in every case

The blood examination is necessary to exclude other diseases, but apart from this the decision as to operation should be practically based on the clinical condition of the patient and on the manifestations in the past. The degree of anæmia is of obvious importance. So, too, is a count of white cells, since a leucocytosis, especially with a polynucleosis, is a sign that the bone-marrow is more active than in the presence of a leucopenia A count of platelets is of less importance A study of cases and of those recorded in the literature shows that the decision as to operation can be arrived at properly in the absence of a platelet count

In very severe forms, either acute or chronic, in which operation would be dangerous, blood transfusion should be performed, and the question of operation considered subsequently This procedure may also be carried out in less severe cases

The question whether splenectomy should be performed should be considered in every case of purpura or hæmorrhages, and the decision should depend on the answers to the questions. 1 Is this a case of the hæmorrhagic diathesis? 2 If so, is it of such severity as calls for splenectomy while giving a fair prospect of recovery from the operation?

Summary

1. The conditions due to the hæmorrhagic diathesis include the primary purpuras, cases recorded in the literature under such titles as "chronic," "recurrent" and "hereditary" purpura, and as "essential thrombopenia," some of the ill-defined blood diseases of childhood and some of the forms of local hæmorrhages from the mucous membranes The condition is usually sporadic, but may be hereditary or familial

2 The initial defect is probably abnormal permeability of the endothelium of the small blood-vessels

3 There is no essential difference between the various groups The cases differ in degrees of severity and in the effects of secondary changes

4. Changes in the total number and differential distribution of the blood-cells, in the number of platelets, in the condition of the bone-marrow, and in the size of the spleen are secondary phenomena There are no constant or typical changes

5 Reduction in the number of platelets in any condition is not necessarily followed by hæmorrhages, but is a factor in their occurrence and severity Reduction may occur in any form of purpura and is not a criterion for the separation of a special type

6 Splenectomy is beneficial without being a "cure"

7 The question of splenectomy should be considered in every case of the hæmorrhagic diathesis

The decision as to operation should be based essentially on the clinical condition of the patient in the present and in the past The number of platelets, the size of the spleen, and the bleeding time are of subsidiary importance only In acute forms and with advanced anæmia, blood transfusion should be performed first

The term "angio-staxis" is suggested to include the group of the hæmorrhagic diathesis

THE COMPARATIVE VALUE OF RENAL EFFICIENCY TESTS IN PATIENTS WITH ENLARGED PROSTATES

By JOHN MARRACK, D S O , M C., M D CAMB ,

AND

SYBIL ROBINSON, M B LOND

(From the Hale Clinical Laboratory and the Wards of the London Hospital, E)

ALTHOUGH the use of renal efficiency tests in subjects for prostatectomy has frequently been discussed, yet the relative value of these tests has not, so far as we know, been compared in the same patients The three tests—blood-urea, urea concentration (MacLean) and phenolsulphonephthalein—have been used at the London Hospital for over four years and a summary of results of these tests is given in Table I We do not propose to discuss the surgical aspects of the subjects, but should point out that no operation was performed in most of the cases as they were considered unfit, and that of the 113 cases on whom prostatectomy was performed only 16 died and 11 suffered from serious complications

We have regarded blood-urea as the primary test, partly because we have come to consider it of the greatest value, but also because it is necessary to estimate it when using the urea-concentration test in order to avoid erroneous conclusions.

In group 1 the cases are arranged according to the highest value of blood-urea found In many cases in which a high blood-urea was found on admission the condition improved after a period of treatment; if the blood-urea was again estimated (this, unfortunately, was not done in all the cases) it was found to have fallen to normal limits; in other cases, however the blood-urea remained high and in a few rose from normal to high figures during their period in hospital

The reason for classing the cases according to their highest blood-urea is that a temporary high blood-urea can be regarded as evidence of interference with excretion,[1] and, therefore, of exposure of the kidneys to back pressure and risk of infection, and danger of development of further trouble even when the temporary interference has been removed.

It is obvious from the table that the blood-urea alone is a very valuable index of a patient's fitness for prostatectomy This is even more striking when we take into account that only two cases in group A and five in group B were operated on without an ample period of drainage Among the 61 cases with blood-urea below 40 mg per 100 c cm. (low and medium normal) there were only three deaths (5 per cent.), and in two of these cases the kidneys were normal; among the 101 with blood-urea above 40 mg. per 100 c cm (high normal and abnormal) there were 28 deaths (27 7 per cent).

Did badly, other causes—(*g*) 1 diverticulitis, 1 epididymo-orchitis 1 recto vesical fistula.

We have included in this discussion patients who did badly from causes not directly due to damaged kidneys This may appear unreasonable, but it is evident from this table that such complications are much more likely to occur among the patients with abnormal blood-urea than among those with normal, either because kidney damage renders the patients more liable to the complications—e g , broncho-pneumonia—or because the cause of the complication also causes kidney damage—e g , thrombosis of the coronary arteries.

We have excluded the urea-concentration tests in which the urea concentration was under 2 per cent and the hourly volume over 120 c.cm , as we consider that patients with fairly sound kidneys may fail to attain a concentration of 2 per cent when the volume is above this figure We fully recognise the arbitrary nature of the choice of this limit, and that some method of "weighting" the significance of the urea concentration according to the volume passed would be more just, but we have not attempted this as such weighting, unless done according to some rigid formula, would be apt to degenerate, in a paper such as this, into "cooking" When an hourly volume over 120 c cm was passed the test was often not repeated, as the *surgeon was satisfied* with other tests; hence the number of cases in which the urea concentration is here recorded is only 92 The results of this test are also satisfactory, especially when it is considered that six of the cases in group 2, A, B, and C, that died had very high blood-urea and that, therefore, the normal urea concentration in their urine could not be regarded as evidence of a sound kidney

---

[1] It is true that a high blood-urea may be encountered in diseases such as pneumonia, severe heart failure and intestinal obstruction, also after ingestion of large quantities of urea or even a high protein diet without kidney damage It is unlikely, however that anyone would choose these conditions when performing tests of renal efficiency on patients with enlarged prostates

It was found impossible to classify the results of phenolsulphonephthalein excretion in more detail than is already given in the table In the first place the cases with enlarged prostates often give surprisingly low returns of phenolsulphonephthalein, this may be partly, but not we think completely, explained by incomplete hourly samples, loss of phenolsulphonephthalein by destruction in infected alkaline urine in the bladder, and loss of dye by adhesion to the precipitate when the urine is cleared of blood However, with this limitation we get the valuable result that in group 3, A, only four patients did badly in any way—in three of these patients all the tests were satisfactory—and in group 3, B, in one only was the adverse result directly due to renal inefficiency In group 3 the majority of the cases still did well, and we have found patients with apparently sound kidneys giving very low values and others with undoubted renal damage giving figures of 20 or more So that low figures do not necessarily mean correspondingly damaged kidneys

As we have considered the blood-urea as the primary test we have now to consider to what degree the other tests supplement the blood-urea A certain number of patients with normal blood-urea did badly Can these be eliminated by the urea-concentration tests? Considering only those cases with normal blood-urea (i e, under 50 mg per 100 c cm) we find in group 2, A and B, 19, of whom three did badly, one from renal causes, in group 2, C, 27, of whom seven did badly with two renal; in group 2, D, 18, of whom five did badly with four renal, and in group 2, E, 10, of whom six did badly, three being renal

It may be inferred that if the blood-urea is normal there is more chance of a bad result if the urea concentration lies between 1 5 and 2 per cent and a much greater chance if it lies below 1 5 per cent Our experience is that the urea-concentration test is of much greater value as a supplement to the blood-urea in medical cases; probably the conditions of life are more conducive to retention of urea in prostate cases than in medical cases, so that urea retention occurs with a slighter degree of renal damage

The only value of the phenolsulphonephthalein test appears to be that excretions over 40 are certain evidence of fitness, among the 42 cases in this group there were 10 with blood-urea over 50, 11 with urea concentration 1 5–1 9, and 3 with urea concentration below 1 5; of these all did well except one, who died of hæmorrhage It does, therefore, give information that the other two tests may not give However, there is so great a liability to give low figures when the kidneys are sound that its value as a routine test is questionable

Table II shows cases in which the tests, bad at first, were repeated after some period of drainage either by catheter or cystotomy Unfortunately, the number is small, as in many cases a clinical improvement was regarded as sufficient evidence that the patient had become fit for operation and the tests were not repeated The Cases 4, 6, 10, and 11 illustrate the fact that, though the blood-urea may fall after drainage, the renal efficiency may remain bad and operation may be dangerous

It is in deciding on such cases, in which the blood-urea has fallen to normal on treatment, that the other tests might be expected to be of the greatest value, but the cases cited give little information on this point Cases 4 and 1 illustrate that a normal urea-concentration test is not sufficient evidence that the kidneys are in a satisfactory condition if the blood-urea is high.

Cys = cystotomy Pros = prostatectomy W L = weeks later

We consider that this series of cases illustrates the value of the blood-urea estimation, the urea-concentration test is of some value to supplement the blood-urea, probably most particularly in those cases in which the blood-urea has fallen after treatment, satisfactory conclusions can only be drawn from the phenolsulphonephthalein test when the results are high—such a result can be taken as certain evidence of sound kidneys—but the test is disappointing owing to the frequent occurrence of low results when the kidneys appear to be sound

We are indebted to the surgeons at the London Hospital for permission to make use of their cases

AURICULAR FLUTTER IN INFANCY.

BY F. J POYNTON, M.D , F.R C P. LOND ,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET ,
AND
W G WYLLIE, M D EDIN , M R C P LOND ,
ASSISTANT PHYSICIAN, HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE , LATE REGISTRAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

As far as we are aware the case we are about to describe is the first to be recorded of auricular flutter in an infant So far the age-limits between which cases of auricular flutter have been recognised are from the fifth to the seventy-fourth year, to quote from the work of Dr. W. T Ritchie [1] Flutter of the auricles, however, is probably not the only form of arrhythmia presented on occasion by the following case. as within a short space of time a variety of rhythms has been observed clinically, such as tachycardia extrasystoles, and a wildly disordered state of the cardiac action which can best be described as a delirium cordis On occasions when electrocardiographic tracings were obtainable, auricular flutter was demonstrated No tracings could be taken at times of the greatest cardiac disorder owing to the severity of the patient's symptoms

Description of Case

The patient a male, was first seen at the age of 4 months, and is now 3½ years old. He was born at full term of a normal labour and weighed 9 lb at birth. He is the second youngest of nine children, the eldest being 20 The parents and other children are all healthy In the case of our patient there is a history of the mother having had a bad fall when 7½ months pregnant

When first brought to hospital at 4 months of age the mother stated that he had been irritable and subject to fits of screaming from birth. In these attacks he ' drew himself up into a ball, screamed, and went blue round the mouth." The symptoms were attributed to indigestion and flatulence The duration of individual attacks varied, but might last for half an hour, and were sometimes as frequent as three in a day In the longer attacks he sometimes became rigid.

FIG 2

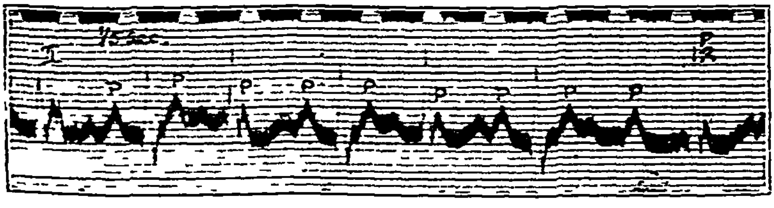

Fig 2 shows 1 . 1, 1 : 2, and 1 . 3 rhythms (lead II.)

Other symptoms described by the mother were breathlessness, vomiting, cyanosis of the fingers, sweating, and " varicose veins " at the root of the neck. On 12 occasions the child has been admitted to hospital because of the severity of the symptoms Countless other attacks have occurred at home for which the mother did not seek help, being well accustomed to their occurrence

In the period of recovery from a severe attack the state of the child is always one of extreme listlessness Examination of the cardiovascular system shows slight bulging of the precordia, extensive pulsation of the precordial interspaces and of the epigastrium, and swelling of the jugular veins. The cardiac dullness reaches great dimensions, extending horizontally from an inch beyond the right sternal border as far to the left as the anterior axillary line and bounded above by the second left costal cartilage. The rapidity and variability of the cardiac rhythm at such times is clinically most perplexing, tachycardia, extrasystoles and phases of " irregular irregularity " displacing each other indiscriminately. The pulse, from being uncountable at the onset of the attack, may show variations from 250 to 100 beats a minute for several days afterwards After a period of two to eight days, the pulse-rate may lie between 80 and 150 At such times extrasystoles are still common, and it is usually after one of these that sudden alterations in the rhythm may be detected. An apical systolic murmur was audible on one occasion only, otherwise there has been no evidence of valvular disorder As a consequence of the great cardiac dilatation the liver enlarges rapidly, and in one of the earlier attacks reached downwards to the level of the umbilicus On this occasion the spleen could not be felt, but in more recent attacks the spleen has seemed to enlarge relatively more than the liver.

The recovery of the child to a state of comfort is not always gradual, but sometimes occurs suddenly with a drop in the pulse-rate and disappearance of the cyanosis Between attacks the child is very active, looks the picture of robust health, and is well grown for his age. Examination also reveals the fact that the heart is considerably larger than normal, and that alterations of rhythm are of common occurrence In a few instances definite acts have coincided with the onset of the cardiac attacks—taking a feeding-bottle, the banging of a door, falling down. Even in the quiescent stages minor stimuli, chiefly emotional such as smiling, may bring about an alteration of the cardiac rhythm. The Wassermann reaction of the blood, tested on two occasions, has been negative. It is of interest to note that the child has had broncho-pneumonia and tonsillitis, both of which ran a normal course.

Electrocardiographs showing Auricular Flutter.

FIG. 1

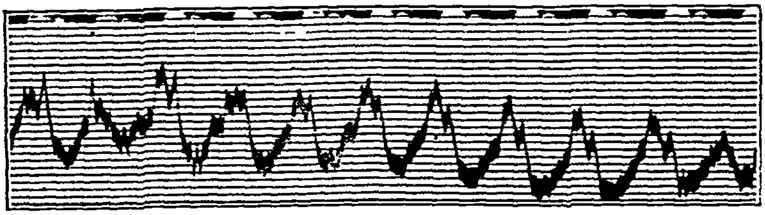

Fig 1 shows a 1 1 rhythm, ventricles responding to each auricular contraction (lead II)

Discussion

This case shows many features of clinical interest, and one of them is the congenital origin of the condition It seems beyond doubt that the symptoms described in the first few weeks of life only differed in degree from those that brought the child to the hospital. The early attacks of abdominal pain with blueness round the mouth, screaming and drawing up of the legs, resemble in some respects those which for many years have been attributed in infancy to flatulence and dyspepsia, results of an unsuitable diet, and they were regarded as such by his mother.

The explanation might be suggested that there existed some unusual cardiac malformation, but we are inclined to dismiss this Although it is well known that grave malformation may occur without the presence of a cardiac murmur, we believe that such anomalous cases, without a murmur and without cyanosis, and yet subject to violent attacks such as this child suffers from almost invariably die in the first year of life This boy, on the other hand, appears to be stronger than he was three years ago, and we can hardly think that a gross cardiac malformation would allow him when at his best to run about and appear almost a normal child.

When he was first admitted to hospital the picture was that of an acute cardiac failure such as we see occasionally resulting from acute influenza, virulent cardiac rheumatism, or profound diphtherial damage is above this figure We fully recognise the arbitrary nature of the choice of this limit, and that some method of "weighting" the significance of the urea concentration according to the volume passed would be more just, but we have not attempted this as such weighting, unless done according to some rigid formula would be apt to degenerate, in a paper such as this, into "cooking" When an hourly volume over 120 c cm was passed the test was often not repeated, as the surgeon was satisfied with other tests; hence the number of cases in which the urea concentration is here recorded is only 92 The results of this test are also satisfactory, especially when it is considered that six of the cases in group 2, A, B, and C, that died had very high blood-urea and that, therefore, the normal urea concentration in their urine could not be regarded as evidence of a sound kidney

---

[1] W. T. Ritchie Auricular Flutter, 1914, p 28

It was found impossible to classify the results of phenolsulphonephthalein excretion in more detail than is already given in the table In the first place the cases with enlarged prostates often give surprisingly low returns of phenolsulphonephthalein, this may be partly, but not we think completely, explained by incomplete hourly samples, loss of phenolsulphonephthalein by destruction in infected alkaline urine in the bladder, and loss of dye by adhesion to the precipitate when the urine is cleared of blood However, with this limitation we get the valuable result that in group 3, A, only four patients did badly in any way—in three of these patients all the tests were satisfactory—and in group 3, B, in one only was the adverse result directly due to renal inefficiency In group 3 the majority of the cases still did well, and we have found patients with apparently sound kidneys giving very low values and others with undoubted renal damage giving figures of 20 or more So that low figures do not necessarily mean correspondingly damaged kidneys

As we have considered the blood-urea as the primary test we have now to consider to what degree the other tests supplement the blood-urea A certain number of patients with normal blood-urea did badly Can these be eliminated by the urea-concentration tests? Considering only those cases with normal blood-urea (i e, under 50 mg per 100 c cm) we find in group 2, A and B, 19, of whom three did badly, one from renal causes, in group 2, C, 27, of whom seven did badly with two renal, in group 2, D, 18, of whom five did badly with four renal, and in group 2, E, 10, of whom six did badly, three being renal

It may be inferred that if the blood-urea is normal there is more chance of a bad result if the urea concentration lies between 1 5 and 2 per cent and a much greater chance if it lies below 1 5 per cent Our experience is that the urea-concentration test is of much greater value as a supplement to the blood-urea in medical cases, probably the conditions of life are more conducive to retention of urea in prostate cases than in medical cases so that urea retention occurs with a slighter degree of renal damage

The only value of the phenolsulphonephthalein test appears to be that excretions over 40 are certain evidence of fitness, among the 42 cases in this group there were 10 with blood-urea over 50, 11 with urea concentration 1 5–1 9, and 3 with urea concentration below 1 5; of these all did well except one, who died of hæmorrhage It does, therefore, give information that the other two tests may not give However, there is so great a liability to give low figures when the kidneys are sound that its value as a routine test is questionable

Table II shows cases in which the tests, bad at first, were repeated after some period of drainage either by catheter or cystotomy Unfortunately, the number is small, as in many cases a clinical improvement was regarded as sufficient evidence that the patient had become fit for operation and the tests were not repeated The Cases 4, 6, 10, and 11 illustrate the fact that, though the blood-urea may fall after drainage, the renal efficiency may remain bad and operation may be dangerous

It is in deciding on such cases, in which the blood-urea has fallen to normal on treatment, that the other tests might be expected to be of the greatest value, but the cases cited give little information on this point Cases 4 and 1 illustrate that a normal urea-concentration test is not sufficient evidence that the kidneys are in a satisfactory condition if the blood-urea is high

We consider that this series of cases illustrates the value of the blood-urea estimation, the urea-concentration test is of some value to supplement the blood-urea, probably most particularly in those cases in which the blood-urea has fallen after treatment, satisfactory conclusions can only be drawn from the phenolsulphonephthalein test when the results are high—such a result can be taken as certain evidence of sound kidneys—but the test is disappointing owing to the frequent occurrence of low results when the kidneys appear to be sound

We are indebted to the surgeons at the London Hospital for permission to make use of their cases

The treatment was commenced in May of last year At the outset careful clinical and X ray examinations were made and in some cases blood sedimentation tests and eosinophil counts were done These were repeated under identical conditions on discharge or if the patient was still under treatment during the month of October.

The average duration of sanatorium treatment before heliotherapy was commenced was 4½ months whilst the duration of treatment by heliotherapy varied from 2½ to 5 months

Technique

In this country the duration and frequency of exposures, and the extent of body surface exposed must depend on the weather and locality The activity of the disease must be considered, but the anatomical extent of disease seems to be of secondary importance, just as it is clinically

At the commencement of treatment the weather was consistently sunny and hot The patients were supplied with bathing drawers and cotton hat. No other equipment was necessary Exposures were made with the patient either on his bed or reclining on a rest-chair on the lawn Erythema doses were avoided as far as possible

In most cases preliminary shade exposures were given Working rapidly up from the feet, whole body shade exposures were reached in a few days These whole body shade exposures were increased up to three separate periods of 15 minutes each with an interval of 10 minutes between each exposure. When this stage was reached the patient was given one period of 5 minutes in full sunlight exposing the whole body as before On the next day two periods of 5 minutes were given and on the third day three periods of 5 minutes with 10 minutes interval between each period

Increases were then made weekly, as follows. First week Three whole body exposures of 5 minutes daily, second week 10 minutes, daily; third week 15 minutes daily; and so on until in favourable cases a maximum exposure of three periods of 30 minutes was reached

Those cases in whom the disease appeared to be least active were allowed to spray each other at the termination of the daily sun treatment with an ordinary garden spray and hose pipe The rationale of this procedure is based on the increased metabolism produced by spraying and bathing at Sir Henry Gauvain s Hayling Island Hospital.[5]

Shade exposures in hot weather are, in my opinion, of considerable value for advanced cases: for not only does the patient get a weak dose of ultra-violet light, but he benefits by the tonic effect of cool moving air impinging on the body. Dr Leonard Hill has shown that metabolism is markedly increased thereby Slight pigmentation may also result, and a toxæmic patient, possibly of the fair freckled type can subsequently be exposed to direct sun with a fair degree of safety

Patients on direct sun exposures were encouraged to continue their exposures on dull cloudy days, and little difficulty was experienced in inducing them to do so Moreover when pigmentation has taken place, the patient is markedly less sensitive to cold

A description of the technique of sun treatment would be incomplete without reference to the importance of adequate supervision, particularly when dealing with cases of active pulmonary disease It is rarely safe to leave the carrying out of the ordered amount of exposure to the patient alone Even the most intelligent patient may be tempted to do too much so great is the sense of well-being experienced.

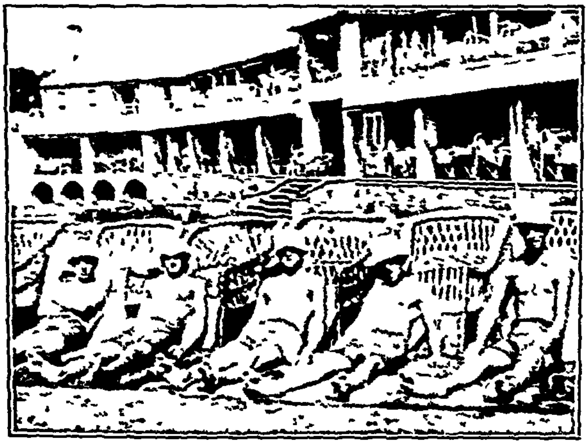
Immediate Effects of Sun Exposures.

Observations were made of the immediate effects of exposure on the temperature, pulse, and blood pressure In most cases there was a definite rise of temperature of about 1° F at the end of exposure; half an hour later this was diminishing to normal. A similar effect on the pulse-rate was noted, though in some cases the rate was lowered and remained low half an hour later.

The systolic blood pressure was lowered immediately after exposure in most cases remaining low half an hour later, but in some cases the pressure had risen again by this time. The effect of cold spraying immediately after exposure was to restore the pressure more quickly, followed in some cases by a slight fall. Most patients did not notice any immediate effect on their symptoms, but two cases complained of a tight feeling in their chest, followed later in the day by loosened sputum.

Effects Noticed During the Course of Heliotherapy

After a few exposures several patients stated that their appetite had improved and that they slept better. There was at first no definite effect on the cough and sputum All appeared to experience a sense of well-being and general fitness especially the less acute cases Perhaps the most noticeable effect was on the mental condition, an improved atmosphere of content and cheeriness being quite obvious As noted above erythema doses were avoided as far as possible, and no case of blistering occurred Any slight rise of evening temperature which could be put down to the effect of exposure was considered an indication for reduction of the exposure But such temperature changes were few Special attention must be drawn to the fact that no cases of hæmoptysis occurred



Pulmonary cases undergoing sun treatment

Clinical Condition at the Termination of Treatment by Heliotherapy

Physical Signs.—In 12 cases these were unchanged, but in the remaining 9 cases there were signs of improvement. Marked unilateral fibrosis and contraction occurred in 4 of these 9 cases whilst in the remaining 5 cases there were less well-marked signs of fibrosis, and disappearance of adventitious signs.

Weight—The weight increased in 15 cases by amounts varying from 2¼ lb to 1 st. 10 lb A slight loss occurred in one case, whilst the remainder showed no change.

Sputum.—The sputum was definitely reduced in quantity in 11 cases, in 2 cases increased, and unchanged in 8 cases

Temperature.—A reduction of temperature was noticed in 6 cases only, but the majority were afebrile (resting) at the commencement of treatment.

Pulse.—The pulse-rate was reduced in 10 cases.

Blood Pressure—The systolic pressure was recorded before and after the course of treatment in 10 cases In no case was there a change of more than 10 mm. In 4 cases the pressure was higher in 2 lower, in 4 unchanged The pressures were taken with a mercury manometer and at the same time of day in each case.

Pigmentation—Ten cases showed good pigmentation 5 cases showed moderate pigmentation whilst the remaining 6 did not pigment at all

Complications—As regards the complications previously mentioned, the following results were obtained. Tuberculous laryngitis, 3 cases (1 case definitely improved); pleura to the cardiac muscle It was not at once apparent that the attacks were recurrent, for all evidence of any infection had to be excluded, and the previous history closely examined

Another interesting point is that, although this child has had numberless attacks of greater or less severity, and although it is probably no exaggeration to say that during the greater part of his life his heart has been beating at about 150 per minute, he is well grown, bright coloured, and as wayward as any healthy child of a corresponding age A case such as this well illustrates the remarkable power of the natural processes of growth and development to assert themselves in the face of grave anomalies in the circulation How remarkable that such a heart could hold its own through an attack of broncho-pneumonia! Few, we think, who saw this child when first admitted could have believed it possible that when he was readmitted with broncho-pneumonia the illness could have ever run an ordinary and satisfactory course Equally interesting is the influence of emotion upon the rate of the heart At one time, if the pulse was counted and the child encouraged to smile, the rate rushed up some 30–40 beats in the minute, and on one occasion when he was tickled he fell back in a minor attack. Throughout his life up to the present the influence of emotion has been prominent

On the other hand, there have been times when the pulse and heart were perfectly regular at 82, and, except for the enlargement—easily enough overlooked in so young a child—the boy might have been passed as healthy. This enlargement of the heart is worth noting, for should it be that at some future date he is found dead, the pathologist would probably be confronted by a large heart with no apparent reason for the fact. Cases of congenital hypertrophy of the heart are known to occur Œdema and cyanosis of the extremities are not common features of such cases The present case bears some resemblance to those described by Howland[2] as idiopathic hypertrophy of the heart in young children He records five fatal cases, from ten months to four years, in which breathlessness, fainting attacks, vomiting, rapid pulse, and occasional cyanosis were among the symptoms observed In none of Howland's cases were any valvular defects found at autopsy The arrhythmias, however, mentioned in the present case were not observed in his

The variations in the rhythm of the heart were remarkable It will be understood that repeated tracings from an infant who invariably cried and struggled lustily with fear were not practicable, and those that were taken might be compared to the examination career of a student, events at certain intervals more or less successful. We are compelled, then, to write of these variations of rhythm in the terms of ordinary careful clinical examination, save for the occasional tracings kindly made for us by Sir Thomas Lewis, Dr Wiltshire, and Dr John Parkinson In a sentence · the study of arrhythmia in this infant seemed to be thrown back into chaos We noted extreme tachycardia, a completely irregular rhythm, numerous extrasystoles, and also a regular normal rate Sometimes, again, the heart would be beating regularly and suddenly trip, when there would follow a complete change in the rhythm

Supraventricular extrasystoles, flutter, and fibrillation according to Ritchie, may be regarded as representing successive stages of abnormal stimulation of the auricles An interesting point in the present case is that all these seemed to occur repeatedly and in no special order during the attacks, if one may suppose that fibrillation was present when the cardiac action was most irregular The pulsus alternans, which with a pulse-rate in the region of 150 is said to be a sign of auricular flutter, was never observed

Treatment

Reviewing the results of treatment, we conclude that complete rest was the great agent Digitalis in small doses was helpful, and on one occasion quinidine was used, the heart rapidly slowed down, but none of the drugs employed mastered the essential difficulty, the prevention of recurrences We would direct attention to Dr Parkinson's tracing here given, which illustrates in an infant an auricular flutter with the ventricles going at the same pace and not, as is usual, an auricle beating at two or three times the rate of the ventricle

This child is still under observation, and better than he was two years ago, but we feel that it would be unwise to hazard a prognosis until he has passed with success through the age when he is exposed to the usual stresses and strains of boyhood

We are indebted to Dr G F. Still for permission to use the notes of the first attack in hospital when the boy was under his care

A NOTE ON

HELIOTHERAPY IN PULMONARY TUBERCULOSIS

By J E WOOD, M R C S Eng,
MEDICAL SUPERINTENDENT, KING GEORGE'S SANATORIUM FOR SAILORS, LIPHOOK, HANTS

So beneficial is heliotherapy in the treatment of non-pulmonary tuberculosis that it is somewhat surprising little use has been made of this auxiliary method of treatment in purely pulmonary disease An idea has arisen that heliotherapy is unsafe, and even definitely harmful, in these cases

In the institution of which I have charge nearly half the beds are occupied by cases of non-pulmonary disease, who make full use of natural sunlight with the usual benefit A proportion of these cases have pulmonary disease in addition to the non-pulmonary lesion Such combined cases require carefully graduated exposures, but appear to derive benefit from heliotherapy in the same way as do the non-pulmonary cases In recent literature various workers have drawn attention to the use of heliotherapy in pulmonary tuberculosis, notably Hudson and Hill,[1] Rollier,[2] McCutcheon,[3] Bronfin [4]

Encouraged by the favourable reports of these observers and by my own experience in cases of little activity, a series of pulmonary cases of all types were carefully subjected to heliotherapy during the summer of 1925, with the object of determining whether any definite benefit could be obtained, and observing what ill-effect, if any, might arise from such treatment in cases of active disease.

Selection of Cases

In the first place exposures were given to afebrile ambulant cases only, but all had bilateral disease No ill-effect being observed in this type of case, exposures were given cautiously to cases confined to bed and still slightly febrile It was found that these cases could be exposed for short periods without reaction The presence of slight fever and toxæmia does not necessarily contra-indicate exposure under proper control, although such cases are best exposed to indirect sunlight, as indicated below Several cases had lesions in addition to the pulmonary disease of such a nature as to entail, in ordinary circumstances, a particularly bad prognosis No fewer than seven cases were of the fair, freckled type

Heliotherapy was tried in 21 cases, which were classified by the Ministry of Health *classification*, as follows —

Class A —No tubercle bacilli in sputum, 4

Class B —Tubercle bacilli present in sputum Group 1, nil, Group 2, 8, Group 3, 9, *total*, 21

Complications were present in 11 of these cases, and were as follows —

Tuberculous laryngitis, 3, pleural effusion 3, multiple non-pulmonary lesions, 2, tuberculous peritonitis, 1, rectal fistula, 1, tuberculous empyema, with sinus, 1 have been used for all these experiments, and the tumour has grown progressively in every case

It may be considered from these experiments that very large doses of X rays (five times that needed for a lethal action on other malignant growths) appear to have no appreciable effect on Rous's chicken sarcoma. Other experiments show that the virus of this tumour, when treated separately, is very resistant to X rays. If a similar virus were present in malignant growths in the mouse, rat, or man, we should have to explain why a dose of X rays will prevent the growth of these tumours, while five times as much has no effect on the growth of the Rous sarcoma It may be that the animal tumours do not contain a similar virus to the Rous, or that its susceptibility to X rays depends upon the tissue in which it exists, or that there is some substance, at present unrecognised, essential to the growth of these tumours which is easily affected by X rays

THE TECHNIQUE OF BLOOD TRANSFUSION.

BY PAUL C GIBSON, MD, BSc, M.R C P LOND,

MEDICAL FIRST ASSISTANT, LONDON HOSPITAL.

IN the past transfusion of blood has had its most striking successes as an emergency operation in the hands of the surgeon For a long time the dangers and difficulties with which it was associated precluded to a great extent its adoption by the physician for the treatment of chronic disease. The discovery of the blood groups enlightened us as to the nature of incompatibility, and, later, the introduction of the citrate method provided a means of avoiding the most troublesome difficulty But it is clear that the technique needs still further improvement in order that its field of action may be extended from the operating theatre to the ward. The main object of this investigation—which is based upon 40 cases transfused by the citrate method—is the solution of this technical problem I have endeavoured to devise a method of transfusion which may be carried out in the wards with safety and reasonable certainty of success, without the need of skilled assistance, independent of strictly aseptic conditions and not requiring elaborate apparatus, difficult to improvise and difficult to sterilise.

Methods.

Of the methods that have been brought forward from time to time there are three that I would like to recall. In 1919 Fleming and Porteous[1] recorded their experience of blood transfusion as carried out by the use of Robertson's apparatus. This consists of a cylindrical bottle connected by three pieces of tubing to the collecting needle, the delivering needle, and a bellows respectively. This apparatus has the great virtue of simplicity, but in my experience of apparatus of this kind I have found serious difficulty to arise from clotting of the blood, either in the bottle itself or in the tubing Another method is described by Stansfeld,[2] in which the citrate joins the blood as near the vein as possible. But the apparatus is too elaborate, it is adapted for use with small quantities of citrate only, and there is no way of keeping the blood warm Then Keynes[3] introduced a method which was a great advance in technique; I have used it on 35 occasions, modified, as described below, in the last eight of these. But it does not eliminate the clotting difficulty altogether; moreover the open method of collection is used which carries with it the risk of contaminating the blood, for the flask must be held below the level of the donor's arm whence infective material may fall into it.

Precautions

With the object of this investigation in view, it seems that the direction in which improvement is indicated is determined by two considerations: (1) the necessity of avoiding contamination; (2) the prevention of clotting The risk of contamination *may be avoided by adapting Robertson's method* of collection to Keynes's method of delivery. The problem, therefore, resolves itself into an endeavour to perfect the means by which the possibility of clotting may be eliminated. To secure this end particular attention must be paid to: (1) the distance to be travelled before blood and citrate mix; (2) the rate of flow from the vein By using the Stansfeld plan, the distance between the needle and the citrate may be reduced to about 2 inches. The rate of flow of the blood depends upon the size of the needle and the rate of filling of the vein The former is dealt with by using a Keynes needle; the latter requires careful consideration. A full vein means a relaxed artery and the calibre of the arteries varies with the emotions Fear, pain and discomfort all militate against success.

Fear is a potent source of difficulty, both in collecting and in delivering the blood Even the most courageous donor may be very much afraid, however indignantly he denies it, and in consequence everything should be done to put him at his ease. The following rules will help to make things go smoothly: (1) Never keep a donor waiting. (2) If he is cold give him a hot drink before taking his blood (3) Have everything in working order before he arrives. (4) Collect the blood in a quiet room without an audience (5) Restrict the parade of instruments and ceremonial to the barest necessities of the case. Similar precautions are necessary for the patient; if he is nervous a preliminary injection of morphia may be given

Pain should be reduced to a minimum by using novocaine, as described below, for both donor and patient.

Discomfort may arise from the posture of the donor and from the pressure applied to his arm during the collection of the blood. He should lie on a couch and should be made as comfortable as possible with pillows for his head, and for the support of the arm which is to be used. The armlet pressure should not be raised above 80 mm Hg—which is the average diastolic pressure—for anything above this will obstruct the artery. But with every care it will not always be possible to ensure a steady flow of blood from the vein. Some contrivance is needed to prevent stagnation of the blood in the tubing.

Apparatus

The apparatus consists of the following pieces:—

Flasks.—(1) The transfusion flask of 1 litre capacity, graduated in 100 c.cm., preferably conical and made of stout glass, having a side tube connecting with pressure and exhaust, respectively. (2) The citrate flask of 200 c.cm. capacity, graduated in 50 c.cm.

Needles—(1) A large Keynes needle for collecting. (2) A smaller needle for delivering the blood. (3) A small silver cannula for use if required.

Air-Locks.—Of similar pattern to that used by Keynes, one for the citrate and the other for the blood. These may be made with the barrels of 1 oz. glass syringes.

Glass Connexions.—(1) Two bent pieces referred to as "siphon tubes." (2) A short piece of tubing, referred to as "the inlet tube," for directing the blood into the transfusion flask. (3) Three short lengths: (*a*) A "window" for interposing immediately before the delivering needle. (*b*) A suction tube. (*c*) An air filter, packed with cotton-wool, for interposing between the suction tube and the flask. (4) A wide bore T-piece. It is advisable to keep a duplicate of this, which is the only essential part that cannot readily be improvised.

Rubber Tubing—The requirements in this respect are sufficiently indicated in the diagram. Special points to notice are: (*a*) Where clips may have to be applied, it is convenient to use moderately thick rubber. (*b*) The connexion between the collecting needle and the T-piece should not be more than 2 inches long

Clips—(1) A screw clip with large milled head, for controlling the flow of citrate. (2) A spring clip for cutting effusion, 3 cases (2 effusions absorbed); multiple non-pulmonary lesions, 2 cases (in both cases one or two lesions healed); tuberculous peritonitis, 1 case (marked improvement); rectal fistula, 1 case (healed), tuberculous empyema, with sinus, 1 case (healed)

Muscular Development.—Workers in non-pulmonary tuberculosis are familiar with the increase of muscular development following on heliotherapy, though the patient is still recumbent and has only a limited range of movement. Careful measurements of the legs were taken accordingly before and after the course of sun treatment. In every case measured there was an increase in the circumference of both thigh and calf, varying from ¼ inch to 1⅝ inches. Palpation of the limbs so measured suggested that there had been a true muscular development, and not merely a deposition of subcutaneous fat.

Clinical Conclusions.—Taking all the above facts into consideration, and avoiding undue optimism as far as possible, it can be stated that definite clinical improvement was evident in 15 of the series of 21 cases.

X Ray Evidence.—X ray photographs were taken before and after the course of heliotherapy in 14 cases. The technique followed in taking the radiographs was identical in each case, and in the initial and final films, faulty interpretation due to varying technique being therefore eliminated. Of the 14 cases, 5 showed X ray evidence of improvement. The remaining 9 showed no change.

Eosinophil Counts.—The eosinophil count is low in acute cases of tuberculosis and is said to be raised as the disease becomes less acute. Counts were done in 9 cases, all of which were low before sun treatment was commenced. After the course of treatment the count was definitely higher in 5 cases.

Conclusion.

A study of these results shows that no ill-effects followed the use of heliotherapy in this series of cases of pulmonary disease. The number of cases is small, but so many of them did well that there can be little doubt the treatment was of definite benefit, either directly or indirectly through the general effect on metabolism. The effect on the mentality of the patient is, in itself, of great value in institutional life. Heliotherapy, therefore, is at our disposal as a valuable auxiliary method of treatment in pulmonary as well as in non-pulmonary disease.

I wish to express my thanks to Sir Henry Gauvain, at whose suggestion this work was commenced, for his advice and encouragement in the preparation of this paper. Also to Dr. Charles Sundell, who has corrected the manuscript, for his kind interest in the work.

THE EFFECT OF X RAYS UPON ROUS CHICKEN TUMOUR.

BY S RUSS, D SC, F INST P,

AND

G M. SCOTT.

(*From the Cancer Research Laboratories, Middlesex Hospital*)

IN several publications during the last six years we have shown that it is possible to give a lethal dose of X rays in vitro to mouse or rat tumours with a fair degree of accuracy. This lethal dose, which we have called L, is the minimum amount of X rays necessary to prevent growth when the tumour is reinoculated into normal susceptible animals; it has been tested a great many times on Jensen's rat sarcoma. A very rapidly growing tumour generally needs a little more radiation than a slowly growing one of the same variety; but even so, the lethal dose does not vary more than ±10 per cent.

Similar experiments have been done with five other animal tumours, Twort's mouse carcinoma, S 37 mouse sarcoma, F 16 rat sarcoma, rat carcinoma R 9 of the Imperial Cancer Research Fund, and a carcinoma of the rat arising in one of the animals in these laboratories. These experiments have shown that none of these tumours need more than the Jensen's rat sarcoma L +30 per cent.

Nearly 90 human cases of malignant disease have been treated by inoculations with X rayed autologous tumours, with the object of immunising them against recurrence of the disease, and as a precaution the dose has been increased to 2 L, but none of these irradiated tumours have grown after this dose.[1]

The following types of growth have been dealt with in this way:—

Carcinomata.—Breast (spheroidal celled, colloid, scirrhus, endothelioma, duct), neck (squamous), tongue (squamous), thyroid (carcinoma); larynx (squamous), liver (columnar), ovary (malignant papilloma)

Sarcomata.—Breast (endothelioma); neck (endothelioma), testis (round-celled), mediastinum (round-celled, lymph adenoma, lymphosarcoma), axillary glands (round-celled), scapula (endothelioma); femur (round-celled, spindle-celled), ilium (spindle-celled, alveolar)

It will be seen from this that the "lethal dose" has been tested on a good many varieties of tumours, and that none has grown when inoculated into susceptible hosts if the dose of radiation has been something between 1 L and 2 L.

Ever since the initial work by Rous on the chicken sarcoma, which bears his name, it has been recognised that this tumour differs from those propagated in rats and mice in the fact that a cell-free filtrate, obtained from the tumour, when inoculated into chickens, reproduces tumours indistinguishable from those produced by the inoculation of the actively growing cells.[2] It has also been shown that the filtrate can be dried and kept for some time, and will even then still produce tumours.

In view of Gye's recent experimental work on this tumour[3] and the bearing his conclusions might have upon the radiotherapy of malignant growths, the following experiments were made:—

A Rous chicken sarcoma was excised and exposed to X rays of the same character and intensity as those used for the rat, mouse, and human tumours, the length of time was 50′=1 L; small pieces of the irradiated tumour were then inoculated into the left breasts of six young fowls. Control pieces were inoculated into the right breasts of two of them. All the tumours grew rapidly and there was no apparent difference between the behaviour of the irradiated and control tumours.

Similar experiments were carried out, increasing the dose of X rays, first to 1 5 L., then 2 L. and 3 L, and finally to 5 L. Even after a dose five times the lethal, no difference could be detected with certainty in the rate of growth, or size of the tumours, the number of metastases, or the rapidity with which the birds died. The data in the table show the comparative rates of growth of the irradiated (dose 5 L) and control tumours.

—	Time after inoculation.		
	9 days	13 days	16 days
	cm.	cm	cm
Experimental— Chicken 1	2 5×1 0	4 0×2 5	5 0×3 0
2	2 0×1·0	4 5×2 0	5 0×2 5
3	3 0×2·0	4 5×3 0	5 5×3 0
4	2 0×1 5	3 0×2 0	4 0×2 5
Control— Chicken 1	1 5×1 0	3 5×2 5	6 0×3·0
2	1 5×1·0	3 5×2 5	4 5×3·0

N B—It is very difficult to make accurate measurements of these tumours as the edge is not very clearly defined. Two measurements have been taken at right angles to each other and estimated to the nearest half centimetre.

In order to see whether the cell-free virus could be affected in any way by X rays, some of this (kindly prepared for us by Dr S L Baker) was exposed at the same time as the tumour, receiving 2 L and 3 L doses; in both cases 0 5 c cm of the X rayed filtrate produced just as large tumours as the same quantity of control fluid. A lethal dose of X rays of a slightly harder type was given to a Rous tumour in vivo, the rest of the fowl being screened with lead; this had apparently no effect on the subsequent behaviour of the tumour. Black leghorn fowls of the same strain help in carrying out the transfusions The complete apparatus, including the thermostat, may be obtained from Messrs Down Bros , Ltd , 21–23, St Thomas's-street, S E 1.

THE CONTROL OF ENTERIC FEVER IN MENTAL HOSPITALS

BY C A. HOGG, M B , M CH EDIN ,
INSPECTOR-GENERAL OF MENTAL HOSPITALS, NEW SOUTH WALES ,
AND
OLIVER LATHAM, M B , M CH SYDNEY,
PATHOLOGIST, DEPARTMENT OF MENTAL HOSPITALS, GOVERNMENT OF NEW SOUTH WALES

IN a recent number of THE LANCET the Director of the Research Institute in Glasgow, referring to the continued outbreaks of enteric fever and the number of carriers isolated in a certain Scotch asylum, makes the statement " Typhoid will come to occupy the position dysentery once held in our mental hospitals if drastic steps are not taken to deal with it." The mental hospitals in New South Wales during the last 25 years have had to face the same problems The incidence of typhoid fever was reduced from 241 cases, among both patients and staff during the pre-inoculation period of 1900–14 inclusive, to 12 in the post-inoculation period of 1915–24 inclusive, or, excluding the uninoculated, to a total of two , during this period the staff and patients combined had increased from about 4530 to nearly 8700 It would thus appear that one drastic method—general antityphoid inoculation—will solve the problem

Historical Data

This 25-year period started with a total of six mental hospitals in New South Wales, but since 1909 three others have come into being It was in connexion with an outbreak of enteric in the family of the sanitary (night soil) attendant and female staff of one of these newly founded hospitals (Stockton) in 1911 that antityphoid inoculation was inaugurated This hospital had been started in 1909 by the admission of some 64 quiet old female dement transfers from metropolitan asylums No ill-health occurred until shortly after the transfer thither of some 60 imbecile girls from the neighbouring mental hospital of Newcastle, where enteric fever and enteritis had been chronic among its imbecile and bedridden idiot population from its earliest history Some carrier seems to have been brought across, for, in a short time, four members of the family of the sanitary attendant, three of the female staff, and two of the girl inmates developed the disease

It is interesting to note that none of the old dements in the other division became infected or gave a positive Widal reaction, and no carriers were discovered among the many recent imbecile admissions who gave positive Widal reactions in their serums Since antityphoid inoculation of the whole hospital —patients, staff, and families—there has been no typhoid, although the *pan* system of sewerage still obtains and the water-supply is still from deep wells in the sand.

Immediately after this the inhabitants of the neighbouring asylum, Newcastle, were inoculated, and only one case has been recorded since—i e , in 1913 The newly opened hospitals of Morrisset and Rabbit Island had their inmates, both patients and staff, inoculated, and in neither has a case been reported

The Remaining Mental Hospitals

Parramatta and Gladesville have had isolated outbreaks and were tardy and diffident about initiating inoculation ; in the latter, during one epidemic, a carrier was discovered by the Board of Health, and the former has also experienced serious outbreaks of dysentery. as many as 70 in one season Rydalmere M H , has had cases of enteric almost every year, and a carrier was carefully but vainly searched for ; nevertheless only one case has occurred among the inoculated since 1914

In Kenmore M H a patient (L) developed typhoid in the autumn of 1909 This relatively modern mental hospital had been typhoid-free till 1906, when a case occurred, and there was one in 1907 and two others in 1909 The patient was subsequently proved by the Board of Health to be a carrier, and after the mischief started he was taken over by the civil authorities The Kenmore outbreak in 1910, traced to him, proved to be the largest in our history ; 57 cases, including 10 staff, occurred in that year A recrudescence in 1913 brought in antityphoid inoculation, since when no case has been recorded

An interesting epidemic took place in 1914 and early 1915 in Callan Park Mental Hospital, which up to then had had cases yearly A careful investigation by a resident medical officer, Dr H H Nowland, directed attention to a certain group of patients, one of whom was found by our laboratory to be passing almost pure cultures of the *B typhosus* in his fæces He also was removed and looked after by the health authorities while we started preventive inoculation. Only one case has been reported since and that occurred in a newly arrived and uninoculated attendant

Other Data Bearing on the Reduction of Typhoid

Examination of the records for the whole State of New South Wales shows a gradual decline of the typhoid rate from 34 per 10,000 in 1903 to about 4 per 10,000 in 1924 No doubt the gradual introduction of the water-carriage supplies in metropolitan areas is largely responsible for this, but in many bush townships and country districts the old conditions still obtain We must also take into account the inoculation of the staffs of many general hospitals and the vigorous following up of carriers, following on a better knowledge of the carrier problem and the general efficiency of the department of public health in New South Wales Some of our medical superintendents have ascribed our reduction rates solely to the gradual introduction of the water carriage of sewerage, but in two instances fresh outbreaks in hospitals, where for this reason inoculation had been delayed, caused a complete volte face, the laboratory receiving peremptory orders to inoculate. The water-supply, although inquired into, has rarely been blamed and has in most cases remained a constant factor, and nearly all the hospitals have their own milk-supply. Some cases were believed to have been traced to handling infected soiled clothes and in crowded wards mental patients who are carriers have many opportunities of passing infected articles about.

It may be suggested that some cases are missed and others suppressed, but it is scarcely likely that this is more so than formerly, except where inoculation completely masks the usual clinical symptoms and signs Dr Penfold, of the Commonwealth Laboratory, holds that " asylum dysentery " is usually of the Flexner type, in contradistinction to work done previously in these hospitals which tended to show that it was of the Shiga type Should this be so, anti-Flexner vaccines and serum will also be made available for our patients The staff are very rarely affected. For many years notification of these diseases has been compulsory.

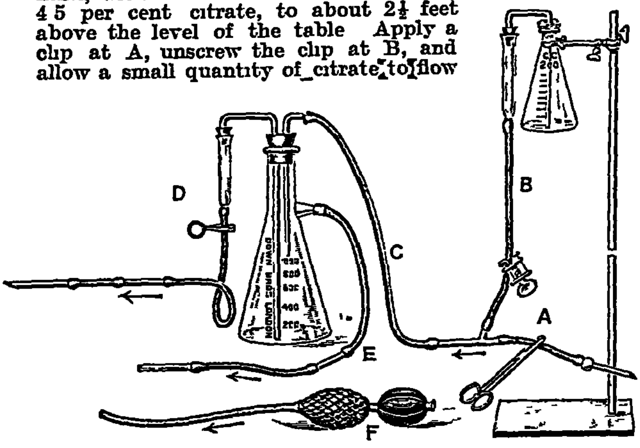
Method of Inoculation

Since the doses of 1000 million typhoid and 750 million paratyphoid A and B per c cm as recommended by the Army authorities are given to medically picked specially fit men, it was considered enough to make up our vaccine so that each cubic centimetre contained 1000 million organisms, 500 million typhoid and 250 million each paratyphoid A and B in 0 5 per cent carbolic acid in normal saline, unheated. As a rule, the first dose was ½ c.cm , followed at intervals of seven days by two doses of 1 c.cm. and repeated every three years Little trouble was experienced if off the delivering tube during collection (3) Three Spencer Wells forceps, with serrations ground down, for use as required These are easy to manipulate with one hand

A Double Bellows, an Upright Stand, a Thermostat —The thermostat is a great convenience, but it is not a necessity, a bowl of hot water can be made to serve the same purpose The pattern I have used was made for me by Mr Daniels, the theatre supervisor at the London Hospital It does not appear in the diagram, but it may be obtained with the rest of the apparatus It is an electrical contrivance, adapted by means of suitable resistance wire to maintain a temperature of 110° F It is fitted with clips to grip the flask and restrain its buoyancy as it empties

Technique

To Start the Citrate Siphon —Fill the air-lock (B) and its rubber continuation with 4 5 per cent sodium citrate Fix the cork attaching it to the glass siphon tube as firmly as possible, and introduce the long arm of the glass tube, through the gauze plug, into the citrate flask, making sure that it reaches the bottom Elevate the flask, with its content of 200 c cm of 4 5 per cent citrate, to about 2½ feet above the level of the table Apply a clip at A, unscrew the clip at B, and allow a small quantity of citrate to flow into the transfusion flask Apply a clip at C and release A Wash through the needle Apply a clip at A and release C Screw up the clip at B The apparatus is then ready for collecting the blood



To Collect the Blood —Apply the armlet of an aneroid sphygmomanometer well above the bend of the elbow Cleanse the skin with ether and paint with iodine Inject a few drops of novocaine (2 per cent.) intradermically at the site chosen for puncture Make a nick through the skin with a sharp knife, right down to the wall of the vein Raise the pressure in the armlet to 80 mm Insert the needle boldly When it is felt to enter the vein release the clip at A Blood should appear in the T-piece When the blood is flowing freely adjust the screw clip to give a continuous succession of drops of citrate The citrate siphon should deliver 100 c cm for every 400 c cm of blood Suction is rarely needed Its effect is to increase the proportion of citrate The flow of blood, when using a big needle, is mainly determined by the rate at which the vein is filling This is not influenced by suction The suction tube E should therefore be left open and lying handy for use if required

If the Flow of Citrate should Stop it may be restarted in one of the following ways (1) By unscrewing the clip at B, which is usually effective (2) By elevating the citrate flask (3) By lowering the pressure in the armlet

If the Flow of Blood should Stop —Immediately apply a clip at C and try to wash a little citrate into the donor's vein. To do this it may be necessary to lower the pressure in the armlet If this is unsuccessful it does not necessarily mean that the needle itself is obstructed In any case do not wait, but at once apply a clip at A and allow the flow of citrate to wash the tube C clear of blood Then release A, and if no blood flows screw off the citrate Raise the armlet pressure to 80 mm Instruct the donor to clench his hand vigorously for a second or two, then to relax completely while counting 5 slowly, and to repeat as required If there is no flow of blood and the adjacent veins are seen to be full, either the needle has slipped out of position or clotting has occurred Push the needle on gently, and if this is ineffective withdraw it a little If, after these manipulations, there is still no flow of blood, it must be assumed, provided that the veins are full, that a clot is obstructing the needle Do not waste time in futile manipulations, but release the pressure in the armlet and withdraw the needle If sufficient blood has not been obtained, a further attempt should be made on the other arm

To Deliver the Blood —Wash through the inlet tube with citrate and disconnect C from the T-piece Transfer the spring clip from D to C Place the flask in the thermostat, this should be filled with water at a temperature of 115° to allow for cooling while the blood is being carried to the ward Replace the suction tube by the bellows Fill the air-lock D with a suitable sterile, isotonic solution. I have used 10 per cent dextrose in some cases and normal saline in the others, and make sure that there are no air bubbles in the tubing The rest of the operation is carried out in the usual way

The Vein of Election —The median basilic or the median cephalic vein should be used if possible. It is courting failure at the outset to attempt entry into any other vein, even though it may appear more prominent or more conveniently situated

The Rate of Transfusion —At first the blood should be given drop by drop, there is no reason for hurry If novocaine has been used, there will be no local discomfort A good average rate is 500 c cm. in half an hour

The Amount Transfused —The importance of this would appear to depend upon the nature of the case In aplastic anæmia the best result was obtained with large transfusions, frequently repeated But in other cases—in which there was no aplasia of the hæmopoietic system—the amount used seemed to bear very little relation to the effect produced It is well to begin with a small amount, about 150 c cm , and gradually to increase it, in subsequent injections

Checking Compatibility

It is now believed that the catastrophes associated with transfusion of blood may be avoided by careful attention to grouping Recent work has shown that the four groups are not so clearly defined as was formerly thought to be the case While investigating this question Jones and Glynn[4] found that, out of 40 cases examined, 7 individuals showed agglutination with blood from members of their own group This bears out the experience of many observers that complete reliance cannot be placed on stock grouping It is, therefore, of great importance to check compatibility in each case immediately before the transfusion is performed For this purpose I have used the following simple macroscopic test in every case in this series The procedure only takes about 15 minutes from beginning to end

Collect a few drops of blood from the patient's finger with a capillary pipette. Mix with 4 5 per cent. sodium citrate, in the proportion of 1 part of citrate to 3 parts of blood, in a small receptacle such as is used for collecting blood in Strong's method of blood counting When the donor arrives, collect a sample of his blood in the same way Then mix thoroughly equal volumes of the two samples on a glass slide, and leave for two minutes If after this interval no clumping is visible the test is considered to be satisfactory If there is any suggestion of clumping, examine a drop of the mixture with the low power of the microscope A few isolated clumps, observed after the lapse of two minutes, may probably be neglected without risk

In every case I have used a donor of the same group as the patient—except in cases of emergency there is no reason for doing otherwise—and I have not met with any of the serious symptoms usually associated with incompatibility With the aid of this improved apparatus it is intended to investigate the effect of blood transfusion on the course of certain diseases, and guided by the experience so gained, to pursue the research still further in the treatment of selected cases At present it cannot be said that the conditions necessary for success with this kind of treatment have been fully investigated Although, in the past, the results have not been such as to encourage any sanguine hope for the future development of therapeutic transfusion, it is at any rate desirable that the remedy should be given a careful and exhaustive trial before it is decided finally to abandon it, as a measure which, except in the limited field of surgical emergencies, has been tried and found wanting

This investigation was undertaken at the London Hospital, and the cases were under the care of Dr R C B Wall and Dr J Parkinson, to whom I am indebted for much kind advice and for permission to record the results obtained I would also express my thanks to Messrs Burrell, Fysh, and Nissé for their

were so terrified that no reassurance had any effect, and abortion was induced It could seldom, if ever, be right to tell a patient that it would be impossible for her to survive another pregnancy.

Obstetric Indications

The obstetric indications were comparatively few and unimportant

Toxæmic Vomiting —By this he meant persistent vomiting with definite signs of toxæmia, such as heavy albuminuria, raised blood pressure, pyrexia, and wasting It was rare for this to be incurable by medical means

Vesicular Mole and Missed Abortion —These were invariable indications for induction of abortion, and the castor oil and quinine method was eminently suitable

Hæmorrhage —Very free hæmorrhage in the early months of pregnancy did not in all cases result in abortion Persistence of bleeding was more serious for the ovum than an initial smart hæmorrhage

Methods of Terminating Pregnancy

Dr J D **BARRIS** surveyed the various methods of inducing abortion These were (1) the slow methods of dilatation, plugging, and the use of bougies and drugs, and (2) rapid dilatation, vaginal hysterotomy, and Cæsarean section The uterus should be allowed to expel its contents spontaneously; to drag out the ovum by force brought a risk of hæmorrhage and sepsis His choice was determined by the urgency of the need for termination and by the stage of the pregnancy Before the end of the third month the fœtal head was small and easily collapsible, and rapid methods might be used, especially as urgency was more likely early in the pregnancy Immediate evacuation was the best of these, using the laminaria tent Strict surgical precautions should be taken, and the instruments should have no sharp points The curette should be blunt Ether or gas-oxygen were better than chloroform After the end of the third month evacuation was more difficult and portions of the fœtus were liable to be left behind Dilatation and evacuation were therefore very dangerous, although they might be used in urgent cases Vaginal hysterotomy made it possible to empty the uterus completely and was preferable to Cæsarean section He had not found castor oil and quinine so reliable as the small bag and pituitary extract For vesicular mole he had found Cæsarean section very satisfactory

Ethical Considerations.

Prof **LOUISE MCILROY** (London) pointed out that generalisation on the question of when premature termination was desirable was useless, and pleaded for the treatment of the patient rather than of the disease Nevertheless she regarded induction as a dire necessity and as a confession of failure, and before resorting to it every factor in the patient's condition should be considered Fear of pregnancy was largely due to a deep-seated idea that pregnancy was a calamity, and education would in time correct this We now had many good substitutes for artificial abortion No one, for instance, induced nowadays for retroverted uterus or diabetes Sympathy for a tragic case should not betray the practitioner into criminal action Cases of hyperemesis who were worried by bad home conditions were often relieved by isolation, and even when vomiting was due to toxæmia she did not recommend induction Phthisical patients should promise not to have another pregnancy after abortion An artificial pneumothorax should be tried before abortion was induced The slow X ray method of sterilisation was satisfactory for them She had given up sterilisation after Cæsarean section for heart disease Heart disease rarely caused death at the puerperium, and the proper treatment was not induction, but rest for the last ten weeks This was often a godsend to a working woman Induction was indicated if nephritis was very far gone, and in pyelitis in late pregnancy when the patient had only one kidney left Toxæmias of pregnancy or hydramnios were hardly ever indications, and two of her patients with encephalitis lethargica had been no worse for their confinement Acute fear, and the mental state of a woman who was pregnant through rape, were not indications for artificial termination Methods should be slow Tents reduced the risk of sepsis and were preferable, and she had found the "penny balloon" method a good one Rapid methods were only admissible if the ovum were dead

The Mental Indications

Dr R H **COLE** held that mental symptoms hardly ever justified induction of abortion, but this might be performed if an obsessional fear was so overpowering as to endanger life He relied on a change of surroundings

Tuberculosis

Dr R. A. **YOUNG** said that the question of abortion for tuberculosis was very controversial and hedged about with aphorisms, which, however, were based rather on individual feeling than on statistics, and took no account of whether the disease were active or arrested If it had been long arrested the patient might proceed, but even if it were active, induction was as likely as labour to cause death The physician should consider all factors and perform all tests, and then consult with the psychiatrist and the obstetrician. Rest in bed would often dispose of symptoms that seemed to indicate interference Treatment must not be stopped because the patient was pregnant, but rather it should be pursued more energetically Any operation was to be deprecated Pinard's aphorism, "Treat the disease and manage the pregnancy," contained much real wisdom, as also did the statement "Prevention is better than abortion"

Cardiac Indications

Dr F W **PRICE** spoke on the cardiac indications with reference only to the question of risk to the mother's life Pregnancy, labour, and the puerperium laid a strain even on the healthy heart, and a certain amount of relative tricuspid incompetence might occur from time to time "Crepitations" over the bases, which disappeared after a few breaths, did not indicate œdema of the lungs Varicosity of the veins, shortness of breath after the twenty-eighth week, or œdema below the knees were not indications of cardiac failure in pregnancy, nor were displacement of the apex beat and left border, increased transverse diameter, or a systolic murmur in the tricuspid area On the whole heart cases bore child-bearing surprisingly well. It was essential to remember that the cause of cardiac failure lay in the myocardium, and it was of extreme importance to find how the heart responded to effort Prognostic indications of value were the modification of the pulse and blood pressure, the size of the heart, the pulse pressure in aortic incompetence, the length of the presystolic murmur, and the presence and length of a diastolic murmur in mitral stenosis

Irregular Action of the Heart —Pregnancy should be terminated in complete auriculo-ventricular or inter-ventricular block if the patient had syncopal attacks When a pulsus alternans was *not associated* with a severe grade of tachycardia it called for complete and prolonged rest, and if this be impossible or unsuccessful abortion should be induced. In auricular fibrillation it depended on the ventricular rate, the degree of cardiac failure, and the response to digitalis therapy In auricular flutter it depended on the response to treatment When there was paroxysmal tachycardia the factors for consideration were (1) coexisting chronic myocardial or valvular disease and its nature and degree, (2) the duration of previous attacks and the ventricular rate and degree of failure in them; (3) reaction to treatment

Chronic Valvular Disease —Mitral stenosis was the most serious form, and abortion was justified in severe cases with very small pulse, and a murmur beginning immediately after the second sound and continuing all through ventricular diastole and auricular systole, or if there were also auricular fibrillation, mitral incompetence, or chronic adhesive pericarditis Pregnancy might continue in cases of mitral incompetence the patients were lined up out of doors, using a fine Schimmel needle which was sterilised after each dose by wiping with wool and methylated spirit; Dover's powder and phenacetin were given if the reaction proved severe That the three years' interval might be the best compromise, apart from trench life in military services, would seem suggested by the fact that a case occurred early in 1925 in a female patient three years and seven months after her last dose

Summary

While there has been a more or less steady decline in the incidence of typhoid fever in the State of New South Wales since 1903, individual cases and epidemics have recurred in our mental hospitals until the advent of antityphoid inoculation In the last ten years only 12 cases were observed and in the inoculated only two, while the hospital population has increased over 90 per cent The little extra work and convenience entailed seem a small price to pay for the practical banishment of such a disease from mental patients

Evidence seems to show that both patient and nurse are especially liable to infection on their first entry to a mental hospital; steps should therefore be taken to insure their adequate protection as soon as possible after arrival This was especially true of the aments at Newcastle Asylum at all ages, the records show that deaths from intestinal complaints used to be common and are now rare

It is with mixed feelings we have to record that in 1914–15 our lunatics were better protected against the typhoid group than many of our soldiers in Egypt and the Peninsula

BRITISH MEDICAL ASSOCIATION

ANNUAL MEETING AT NOTTINGHAM.

(Continued from p 335)

SECTION OF OBSTETRICS AND GYNÆCOLOGY

WEDNESDAY, JULY 21ST

This Section met, with Mr COMYNS BERKELEY in the chair, to discuss the

INDICATIONS AND METHODS FOR TERMINATION OF PREGNANCY BEFORE THE VIABILITY OF THE CHILD

The discussion was opened by Dr T W EDEN, who said that it was not possible to lay down strict rules, and it was therefore of interest to consider from time to time what extent of agreement there was on the indications for inducing abortion He did not feel the attitude should be too rigid; it should be clear to ailing women, to whom pregnancy might be a long-drawn and painful penance, that the profession had sympathetically weighed their position He thought it might at times be right to terminate pregnancy even if the mother were not suffering from any condition which could, strictly speaking, be called disease, but such cases required the most careful consideration

General Indications

The lists of indications were in the text-books, he would take up a few of the more important ones

Phthisis.—Obstetricians of all countries differed as to the necessity for terminating pregnancy in pulmonary tuberculosis The views of physicians must be taken into account Osler taught that a woman with arrested or cured phthisis with bad family history and poor physique ran grave risk in becoming pregnant, if there were active disease pregnancy usually hastened the process Osler quoted Dubois "A woman threatened by phthisis may bear the first accouchement well, the second with difficulty, the third never" The speaker was prepared to act on Osler's views Phthisical mothers usually bore well-developed and healthy children, although tubercle bacilli could pass through the placental filter, but the expectation of life was not normal Couvelaire stated that 38 per cent of children born to mothers with active phthisis did not survive their first month, being born with a "diminished coefficient of vitality" Dr Ward, tuberculosis officer for South Devon, found that among 372 such infants 34 per cent became definitely tuberculous and a further 21 per cent were suspect, of the 34 per cent one-fourth died He also concluded that children of a tuberculous mother were seven times more likely to become tuberculous than were those of healthy mothers, and that of tuberculous women who became pregnant over 50 per cent were made definitely worse, while 19 per cent were improved. It was not to the advantage of the community that children should be born with a risk of tuberculosis seven times greater than the normal

Chronic Nephritis—Pregnancy was always attended by certain very definite risks in cases of chronic nephritis Complete breakdown of the renal function might occur, leading up to uræmic convulsions, an intercurrent attack of acute nephritis might supervene, and, if these were survived, the working capacity of the kidneys was permanently reduced Accidental hæmorrhage, especially the toxæmic form with interstitial hæmorrhage and necrosis of uterine muscle, occurred in a relatively high proportion of cases The fœtal risks were also very heavy, about 40 per cent died from prematurity or from the results of transplacental intoxication Nevertheless it must be remembered that these conditions were risks and not certainties, the time might come when we could distinguish more clearly the factors which made prognosis grave The hydræmic type of nephritis was much more serious than the azotæmic type In the absence of dropsy in the early months a first pregnancy might be allowed to continue if the blood pressure and the adequacy of renal elimination were most carefully watched In subsequent pregnancies early abortion should be induced if a serious renal breakdown had occurred before In any case the occurrence in early pregnancy of albuminuria and œdema of the renal type justified induction

B Coli Infection of the Urinary Tract—This did not lead to serious developments in its subacute form, although it might cause an acute outbreak of fever during the puerperium.

Diabetes Mellitus—The introduction of insulin had reduced very greatly, without entirely eliminating, the risks of diabetes in pregnancy Glycosuria and lactosuria were not uncommon, but unless accompanied by an increase in the blood sugar and such characteristic symptoms as polyuria, thirst, and wasting, were not diabetes and were always amenable to dietetic treatment

Heart Disease—A young woman with a well compensated valvular lesion would usually pass through one and possibly two pregnancies without serious inconvenience Repeated pregnancies damaged the heart and reduced the expectation of life Abortion might be justified by signs of failure in the early months or by a history of serious breakdown in a previous pregnancy

Diseases of the Nervous System—He had ended pregnancy on the advice of a psychiatrist in cases of former puerperal insanity or border-line cases with a bad family history Such cases were pre-eminently suitable for team work Chorea was not uncommon in pregnancy and was usually amenable to rest, careful feeding, segregation, and arsenic Occasionally abortion might be justified in severe obdurate cases with pyrexia He described a case where the patient had been told that it would be most dangerous to have another child, with the result that she and her relatives should not be done lightly. but he urged its wide use, because it was simple. safe. and unaccompanied by untoward complications and sequelæ, because it gave the only actual test of the power of the uterus and was an attempt to procure the highest aim of the true obstetrician—a natural parturition

Mrs. Rhoda Adamson (Leeds) said that her private patients usually had symmetrical pelves, but hospital cases were more liable to irregular rickety contractions The small flat pelvis was suitable only for Cæsarean section. while the simple flat pelvis permitted labour surprisingly easily if left to Nature. The best case for induction was one with a moderate degree of contraction It should be remembered that a child's head tended to resemble that of its father. and it was worth while to inspect the patient's husband The external measurements were far less important than the relative size of head and pelvis The further the pregnancy was allowed to go the better for the child The doubtful case would very often deliver itself if allowed to try. and so she never performed Cæsarean section before labour in cases of contraction. Immature girls with small pelves should be treated by induction because a normal delivery resulted in general development and enlargement of the pelvis while Cæsarean section. in addition to the wound damage, left the pelvis small.

Discussion.

Dr. English said that contracted pelvis was relatively rare in Singapore owing to the absence of rickets. Some text-books stated that induction from the thirty-eighth to the fortieth week was no great advantage: this was not the case. Cæsarean section was best performed during labour as the lower segment incision was then much easier to make. It was very helpful if practitioners inducing labour in a primipara would give her a note for the guidance of the doctors who attended her subsequent labours.

Prof Louise McIlroy agreed that Cæsarean section should only be done when labour had started, and that the number of a practitioner's operations steadily diminished as his judgment grew. Cæsarean section was a mutilation, done from dire necessity only. She had found that the outlet was the dark horse of obstetrics: the pelvic brim could be estimated antenatally, but trouble with the outlet was usually revealed too late to do anything Some method of measuring it would be a great advance in obstetrics She hardly ever induced before the thirty-eighth week because the immature child stood labour badly and prolapse of the cord was more likely to occur It was difficult. but very necessary, to know the exact date of the pregnancy. Two very difficult problems were the post-mature fœtus and the breech with extended legs. How was the relative size to be estimated in the latter case? Hurrying up labour was very dangerous: patients should not be worn out by bearing down and pulling A long. easy labour was much better for mother and child. She urged sedatives in labour sitz baths. and morphia: she had never seen any ill results from morphia. Measurements were of little importance the whole thing depended on the size and degree of flexion of the head. She had found that pregnant women objected to vaginal examinations, and she regarded this as a natural defence against the dangers of interference with vagina and cervix late in pregnancy.

Methods

The stomach-tube was both useful and safe. X rays had shown it curled up right to the top of the uterus, covering much more space than a bougie ever could. A penny balloon filled with water from a Higginson's syringe was remarkably successful when the head was high. and was very safe. The de Ribes bag was most unsatisfactory Induction by drugs (castor oil and quinine) was safe to recommend to midwives in slight cases of contraction

Mr Evers said that the difficulty was with the borderline primipara where there was nothing to guide the practitioner Help could be obtained from measurements particularly the external conjugate The asymmetrical pelvis was the least suitable for induction. He emphasised the value of examination under an anæsthetic. An analysis of 150 cases of Newcastle primiparæ with head above the brim showed that 12 per cent. had come to Cæsarean section—far too high a figure.

Mr. Rivett said that in many cases it was difficult to say whether there was an actual contraction. and the size of the parents was very important. The very fat young primigravida had fat also in the pelvic tissues and might require Cæsarean section even if the pelvic measurements were normal. The weight of the baby tended to increase with the third. fourth. and fifth pregnancies. It was a great mistake to label a woman "normal multipara." The weight of the baby at birth should always be recorded definitely. The figures of induction cases at Queen Charlotte's Hospital gave corresponding results to those quoted by Mr. Banister: the mortality at 35 weeks and under was over 50 per cent.

Dr. S. W. M. Jones (Wolverhampton) pleaded that general practitioners should give more consideration to induction. There was a prevalent idea that it was a "messy business" He had been disappointed in the castor oil and quinine method. which often failed at the thirty-seventh or thirty-eighth week.

Dr. A B Danby (Birmingham) asked what methods Mr Banister had employed. At the Birmingham Maternity Hospital a No. 4 œsophageal tube had proved satisfactory. The time factor was very important and was shorter with the tube than with bougies Quinine and castor oil had proved unsuccessful in 31·6 per cent of cases on the district. Deflexed heads would often go through quite well when rotated by a pad and binder. A man with a large head should never marry a woman with a small pelvis.

Dr. T. A. Richmond (Stoke) said that there was not a single maternity bed in Staffordshire His rough and ready method. under these circumstances. was 'when in doubt induce.' The types of case that arose were (1) the multipara with a bad obstetric history, (2) the primipara with small pelvis and (3) the post-mature case usually a big athletic woman who was left to go to time and then went over. He had had very good results from giving pituitrin at the time when labour was expected

Mr. Comyns Berkeley said that his experience coincided with Mr. Banister's. A miscarriage in early pregnancy was always attributed to vaginal examination if one had been done. so that it was not only useless but impolitic to attempt any extensive examination before the thirty-sixth week. Analysis of cases of induction at the City of London Hospital had shown the danger of inducing too early.

Prof. McIlroy. in reply to a question. said that when the placenta was attached to the anterior wall it was easy to locate it antenatally by the position of the souffle.

Mrs Adamson. in reply. said that a tight binder might be very useful The students at Leeds were being taught to examine rectally. Castor oil and quinine was not effective before the thirty-eighth week. but was worth trying in the later weeks. In assessing the dose it was important to find out the habit of the patient as regards purgatives. In the factory class of woman the weight of the baby increased until the mother was about 30 She did not regard Cæsarean section. by the paramedian incision. as a mutilating operation. but patients should be kept under supervision in subsequent pregnancies.

Mr Banister. in reply. said he took strong exception to the phrase Once a Cæsarean always a Cæsarean.' He believed that contraction at the outlet was very definite. but rare: it would never be recognised by measurements but could be appreciated manually on examination under anæsthesia. He regarded a breech with extended legs in a primigravida as a definite and legitimate indication for Cæsarean section. He did not think it possible to precipitate a miscarriage by taking pelvic measurements. and it was valuable to know them early. Every vaginal examination performed in pregnancy must be justified by special circumstances and should not be done until induction and aortic stenosis if not due to primary chronic endocarditis Abortion was justified in severe aortic incompetence with great alteration in pulse, blood pressure, and size of heart, especially if the patient was apt to faint on exertion In congenital heart disease it depended on the size of the heart and subjective symptoms

Chronic Myocardial Disease by Itself—The indications for consideration were the size of the heart, syncopal attacks, and the presence of irregularities

Estimation of Cardiac Failure—Four points should always be considered. (1) the degree of cardiac failure, (2) at what stage of pregnancy the symptoms supervened, (3) the immediate cause of the present attack, and (4) response to treatment If the failure were slight the patient could probably go to term without risk If moderate failure occurred during the first three months, without some temporary cause, she would probably be unable to go through, but an attempt might be made Rest was imperative If severe failure occurred in the first half of pregnancy the patient was in danger, but a rest of some months in bed often had surprisingly good results Pregnancy should be terminated if extreme cardiac failure supervened at any time, but apart from this a reasonable period of rest and therapeutic measures should always be tried In any case the heart lesion should be treated first in order to secure better conditions for the operation of abortion

Discussion

Dr R C BUIST (Dundee) pleaded that general practitioners should not foreclose the discussion of a case by expressing an absolute opinion

Mr H EVERS (Newcastle) said he thought it was most important for the profession to take up a conservative attitude towards what he preferred to call embryocide The conditions where it had proved its value beyond doubt were extremely few He did not see why pregnancy and labour should be regarded as an ordeal, and regarded the matter as legal and moral, not ethical nor professional, the patient's reasons for desiring abortion should never be accepted He surveyed the indications for abortion and concluded that the only absolute indications were vesicular mole and nephritis with severe clinical manifestations The infants of phthisical mothers should be segregated from birth Cases of heart disease, vomiting, and nephritis could nearly always be carried on till the child was viable His reasons against the induction of abortion were the very great importance now attached to intra-uterine life, the improvements of modern treatment, and the fact that the so-called dangers of pregnancy in certain conditions were mostly speculative and groundless

Dr B DUNLOP (London) said that for him it was sufficient indication if the mother steadily wished it in spite of all persuasion He was convinced on sociological grounds that it was not in the public interest that medical practitioners should not be free to induce abortion on economic and eugenic grounds

Dr J S ENGLISH (Singapore) described as very satisfactory the method of induction by inserting a No 23 stomach-tube, it was easier to sterilise than gum-elastic, required no anæsthetic usually, and was very sure

Mr L C RIVETT (London) said that in his limited experience of phthisical cases it was the puerperium that was detrimental, and he agreed with Dr Young that only in very severe cases of active tuberculosis was interference warranted The best method to sterilise such patients was X rays, as any anæsthetic was so bad for them He considered that gross deformity of the pelvis, necessitating Cæsarean section at term, was also an indication for abortion if the mother so desired At Queen Charlotte's Hospital he had found heart disease far the most serious complication; cases did not respond to treatment in any way and many died—the majority undelivered He therefore regarded it as a strong indication for early abortion, and thought a miniature Cæsarean section with occlusion of the tubes was the best method Heart cases stood the operation well in early pregnancy

Dr N LOCK (Exeter) said he had found Cæsarean section less strain than normal labour, heart cases always took a well-administered anæsthetic without difficulty.

Mr RIVETT replied that he had not found Cæsarean section make the slightest difference either way in his heart cases He agreed that they stood anæsthetics well and deprecated spinal anæsthesia for them

Mr COMYNS BERKELEY said he regarded it as perfectly disgraceful ever to tell a patient that she must not or could not have another child He agreed with Dr Barris in using a quick method of emptying a small uterus where the hæmorrhage could be controlled The stomach-tube method was good, but liable to lead to very severe bleeding

Dr BARRIS, in reply, said the weak point in slow dilatation in the first three months was that it often produced no effect and had to be constantly repeated, with the probability of having to give an anæsthetic in the end

Dr EDEN, in reply, said there was no such crime as fœticide, and he was more and more impressed with the necessity for taking the broadest possible view. If the public could feel that they would get sympathetic consideration from the medical profession they would not go so much to the criminal abortionist. We could not divest ourselves of responsibility for the generation we were bringing into the world

THURSDAY, JULY 22ND

THE PLACE OF INDUCTION OF PREMATURE LABOUR IN THE TREATMENT OF CONTRACTED PELVIS

Mr J BRIGHT BANISTER, opening the discussion, said that he suspected that Cæsarean section was being employed oftener than was justified in cases of pelvic deformity, and that induction had fallen into unjustifiable disrepute His conclusions were based on 745 cases of induction The maternal mortality had been 1 3 per 1000, so that there was no great risk to the mother The fœtal mortality had been 12 6 per cent, and analysis of the figures revealed the enormous advantage of obtaining natural delivery, the mortality in such cases being less than 8 5 per cent, while among the forceps cases it was 23 4 per cent Of the fatal cases posterior positions were in high percentage The fœtal mortality-rate dropped as the date of induction advanced, except at the end of the series, where the induction had been too long delayed Induction had failed in 24 cases The morbidity-rate was no higher than in normal cases, being just under 4 per cent The most important complication was prolapse of the cord, which was accompanied by a very high fœtal mortality, but this could be attributed as much to the contraction as to the induction

The Date of Induction

Antenatal examination revealed contraction early in pregnancy If the true conjugate were 3¼ in or less induction was contra-indicated The optimum time for induction was estimated by careful consideration of the relative sizes of the presenting part and pelvis, the shape of the pelvis, and the position of the head Such patients should be seen weekly A generally contracted pelvis presaged an earlier induction than a flat one The position of the occiput was an important factor in oblique contraction, if on the narrow side the difficulties would be greatly increased When bimanual examination failed to make the head descend appreciably the patient should be examined under an anæsthetic and the disproportion was then usually found to be less than was thought, and in this case induction should be advised in 14 days' time If no engagement could be obtained induction should be done at once The moulding powers of Nature made it safe to wait until the head would just not enter the brim He did not believe that patients would resent or practitioners grudge these careful examinations Induction also gave valuable information as to the capacity of a uterus to deliver itself and provided grounds for deciding whether to leave or induce at the next parturition Every induction must be judged on its own merits interfered with normal contraction and produced uterine stagnation It was much more serious than menostaxis and could soon produce severe secondary anæmia Curettage was a temporary palliative that was sufficient in puberty, but at the menopause the most useful remedy was radium

Metrostaxis a term the speaker preferred to "metrorrhagia," included all hæmorrhages independent of the menstrual cycle. The blood was bright red, often with large clots—quite different from the menstrual lochia The endometrium generally showed hypertrophy, which might be diffuse or localised in a single polypus, and this pointed to a deeper underlying cause He thought the answer would appear when more was known about the relation of the autonomic nervous system to the uterus and the ovaries Labour or abortion (whether fertile or afertile) might be set up by mental shock; he cited as a typical case that of a woman who had sustained a motor accident. It was uncertain whether the uterine hæmorrhage was due to the mental shock alone or to the attendant hyperthyroidism. Metrostaxis was comparable to gastrostaxis, which was also peculiar to women and bore no relation to the menstrual rhythm Müller's sympathetic vaso-motor centres in the tractus intermedio-lateralis of the medulla, which Castex had shown to be also vasotropic, were probably intimately concerned with these functional hæmorrhages, and these observations opened up a wide field of research The peculiarly embryonic nature of the endometrium made it exceptionally liable to outside changes, and gynæcologists had been too eager to expect abnormal appearances such as hyperplasia as a cause rather than as a result, of continued bleeding Estimation of the blood tolerance of sugar and of the basal metabolic rate provided important data in the investigation of uterine hæmorrhage at periods of unstable equilibrium, especially puberty and the menopause

Discussion

Prof. **Fletcher Shaw** (Manchester) said that in the past it had been the custom to look for the cause of uterine hæmorrhage in the uterus itself; now a much broader view was taken, and physicians had to remember the types of disordered physical function that might occur in or outside the uterus Disordered hæmorrhage fell into four groups: (1) general medical, (2) disordered physiological function, (3) pathological conditions of the endometrium, (4) pathological conditions of the uterine body All our knowledge of the third group had recently had to go on the scrap-heap, as many of the changes regarded previously as pathological were now known to be due to the physiological cycle, while others still classed as pathological were probably due to some cause outside the uterus. He cordially welcomed the new terms suggested by Prof Beckwith Whitehouse, provided other teachers would accept them, and pleaded for a simplified nomenclature for group (4), which could be divided into three types:

(a) *Chronic Metritis* —In a normal healthy uterus there was a balance between the muscular activity and the blood flow through the vessels. In chronic inflammation the muscular tissue was destroyed and replaced by fibrous tissue, so that an inert mass was interposed between the muscle cells and the blood-vessels, resulting in diminished contractile power

(b) *Subinvolution* was much commoner, the history of the hæmorrhage dating from a confinement. In this case there was a large mass of elastic tissue outside the blood-vessels There was no abnormal fibrous tissue—hence the term "fibrosis" was unjustifiable—and no decrease in the muscular tissue This inert elastic tissue underwent, in time, vitreous degeneration, so that it might be absorbed, but if this did not occur it underwent vitreous hypertrophy and regained its staining and elastic properties Sometimes hæmorrhage was not complained of in these cases until the menopause, when the inert body got more and more play through the atrophy of muscular fibres Chronic metritis and subinvolution often occurred in the same uterus, because the same inflammatory process that caused the latter would also cause the former.

(c) *Hypertrophy*—A similar syndrome might occur in a nulliparous woman, and the hæmorrhage was then found to be due to a very thick endometrium, or else to some common cause which had produced both. There was no pathological change save hypertrophy of every tissue, which was probably due to an excessive uterine contraction every month.

Mr **W W. King** (Sheffield) said that endometritis was a ridiculous term that had been used as a scrap-heap for diagnosis; it had put back for years the proper conception of menstrual anomalies He queried the necessity of retaining the term "chronic metritis," for which "chronic subinvolution" could usually be substituted In treatment lutein seemed the best thing for functional hæmorrhages, but glandular extracts were useless by the mouth, except thyroid. Individual cases differed markedly in their reaction to endocrines Injection of hæmoplastic serum had stopped the bleeding of young girls with villous conditions of the endometrium, and in some cases seemed to do permanent good Cotarnine was very useful in hæmorrhage without any gross physical signs Out of 144 cases treated with 1300 to 2000 m c. hours of radium 13 per cent. had further bleeding and 26 per cent. suffered from menopausal symptoms. As radium was supposed to act mainly on the endometrium and not on the ovaries, this raised the question of an internal secretion of the former.

Dr **Rhoda Adamson** (Leeds) said that she had found that girls sent away to the seaside to boarding-school were apt to get bad floodings, which were not improved by the school doctor's treatment, but which cleared up when they came home She had discovered that it was a recognised thing that professional ballet dancers and acrobats had amenorrhœa or almost negligible menstruation while working, but when resting they returned to their ordinary rhythm.

Dr **J. S English** said that he had met cases of amenorrhœa in Singapore who had normal menstruation on returning to England. He had found that large doses of X rays gave very good results

Mr. **L. C. Rivett** (London) said he had found that simple curettage gave temporary relief only. He had not found it possible to separate Prof. Fletcher Shaw's first and second groups clinically, except that a bleeding uterus might be large and flabby or small and hard.

Dr. **M Eames** said she had had most varying results from thyroid administration, and asked how to treat excessive losses at puberty in girls with pulsating thyroids.

Dr **S W. Masley Jones** (Wolverhampton) said that in the absence of modern facilities for treatment he had found good results follow irradiation over the ovarian region, especially for young girls; one case only had failed to respond, and she had subsequently been cured by irradiation of the thyroid For older cases he had successfully used the intra-uterine application of glycerine, which seemed to start involution off again.

Dr **T. H. Richmond** (Stoke) referred to the piling up of cells within the glands, without rupture of the basement membrane, so often found in curettings, and to the good effects of radium on these cases, as if there were some local malignancy.

Dr **Combie Sharp** (Cape Town) said he thought obstetrics and gynæcology were very liable to fashions, and the latest of these was treatment by medicines—e g, pituitary extract, which he considered to be a most dangerous drug—before the child was born.

Mr. **Comyns Berkeley** also welcomed the new terminology, and urged that all teachers should adopt it He had found 250 mg of radium for 20 hours a magnificent treatment for these conditions, but the possibility of sterilisation must not be forgotten. Utriculoplasty had given excellent results, and some of his cases had successfully borne children after it Curettage was the commonest and most hopeless operation for hæmorrhage.

could be immediately carried out He regarded rectal examination as a very grave retrograde step The method he considered best was the gum-elastic bougie No XII , three, if possible, with surgical cleanliness, and no additions, induced labour in from 48–60 hours Castor oil and quinine had a fair measure of success at full time, but was not successful for premature labour He had ceased to regard pituitary extract as dangerous with the advent of the 10 per cent solution, and had had no ill-effects from ¼ c cm of this solution given three-hourly up to 1 c cm

FRIDAY, JULY 23RD

At this meeting of the Section a discussion on the

CAUSES AND TREATMENT OF UTERINE HÆMORRHAGE WITHOUT GROSS PHYSICAL SIGNS

was opened by Prof **BECKWITH WHITEHOUSE** (Birmingham), who said that it was somewhat strange that so little was still known about the facts at the basis of the function of menstruation Nevertheless, there were signs that we were nearing solid ground upon which we could build a structure of sound physiological and pathological knowledge

The Menstrual Function

Our knowledge of the causation and treatment of pathological uterine hæmorrhage must depend primarily on our views on menstruation Many important advances had been made during the last few years, and the recent work of Novak had corroborated the speaker's views of 1914, that at each menstrual function there was a definite shedding of portions of the superficial endometrium, and that the discharge consisted of the autolysed products of this necrosis Prof Whitehouse still believed that the secretion of the uterine glands was concerned in the breaking down of the menstrual clot composed of blood coagulum and tissue débris, and the work of W Shaw had confirmed this view The only modification the speaker desired was that in most cases autolysis began while the separating endometrium was actually in anatomic contact with the deeper layers, and while the extravasated blood was intimately associated with the epithelial débris Thrombolysis was by no means complete, and although the lay mind did not recognise as clots minute coagula in process of solution, it was the exception for clots to be entirely absent throughout the whole menstrual process He agreed with Novak that the desquamation of the mucosa was " a crumbling molecular process," bits of granular degenerated mucosa being shed until nothing was left but the " basalis " and perhaps a few " spongiosa " nests

The Nature of Menstruation

In the light of the most recent research menstruation must still be regarded as an afertile abortion of the non-pregnant decidua It corresponded with the death of the unfertilised ovum, and the commencing retrogression of the corpus luteum Rupture of the follicle and the escape of its liquor marked the beginning of the pre-menstrual hypertrophy of the endometrium, which should correctly be called the " menstrual decidua " It was still unknown whether the stimulus was provided by the hormone of the liquor folliculi, that of the ovum and its attached cells, or that of the developing corpus luteum

He considered the name " menstrual lochia " more appropriate for the discharge Menstruation removed the inhibiting effect of the corpus luteum upon rupture of succeeding follicles, and the cycle was re-established The old theory that the menstrual function was necessary for the reception of the ovum was a pure myth The explanation for fertility during lactation, after the menopause and during pathological amenorrhœa was the same , an ovum maturing late must produce either an afertile abortion (post-menopausal functional hæmorrhage) or else, if it happened to meet a spermatozoon, a post-menopausal pregnancy There was a striking similarity between the menstrual abortion and one during early pregnancy, and, in fact, menstruation was simply the disorderly action of a disappointed ovum

Periodicity of the Menstrual Function

To understand its remarkable periodicity it was necessary to remember that *Homo* was the most highly-specialised organism in existence Evolution had altered woman's sexual rhythm somewhat as scientific breeding and care had altered that of the domestic fowl The cause both of the monthly abortion and of the irregularity at the beginning and end of the sex-life lay in the ovarian follicles Factors that interfered adversely with the maturation and discharge of the ovum were reflected in the menstrual rhythm Halban induced menstruation and altered the rhythm by excising the corpus luteum Most experimental mammals had been changed by domestication from a monœstrous or diœstrous to a polyœstrous rhythm Confusion had arisen partly because in *Homo* fertilisation could take place at any time following the pre-œstrual abortion , the œstrual period was prolonged to reach and include the next pre-gravid state This variation must not influence consideration of the rhythm in lower types , the human sexual instinct was independent of the sexual organs Finally, the accessory genital glands, such as the thyroid and pituitary, were of greater importance in *Homo* Although woman was " built round her ovaries," these were only one link in the metabolic chain

The Uterine Secretion

About the function of the glands of the corporeal endometrium little was known Experiments showed that in some animals at least the uterine secretion was reabsorbed and helped to produce œstrus, but it was unlikely that it played any great part in producing the human sex instinct, which persisted after the menopause and even after removal of the sexual organs Possibly, however, it caused the pelvic hyperæmia of menstrual abortion and of early pregnancy, and autolysed the necrosed decidua and coagula when fertilisation did not occur It could occur without menstruation, but was always associated with it. Some of the confusion that existed about the nature of menstruation was due to the presence of these two separate functions of menstrual hæmorrhage and uterine secretion, of which the second was in a sense complementary to the first

The speaker described experiments in the production of artificial menstruation by excising the corpus luteum from the right ovary of a patient during an exploratory operation

Functional Pathological Uterine Hæmorrhage

His conclusions were based on 200 consecutive cases Pathological hæmorrhage usually fell into one of four groups, in which the periods were frequent, prolonged, severe, or irregular

Epimenorrhœa was the clinical manifestation of a hyperactive sex-complex The ovaries, working at high pressure, produced ova of low vitality, and frequent abortion resulted They were usually hyperplastic and often polycystic The condition was almost physiological at the beginning and end of sex life Curettage was useless The remedy probably lay in inhibiting the accessory sexual glands The speaker was investigating the injection of fresh corpus luteum extracts

Menostaxis, a prolonged period, was analogous to an incomplete fertile abortion Curettings from different parts of the uterus showed the normal post-menstrual phase, active superficial necrosis, and marked pre-menstrual decidua Chronic inflammation of the endometrium predisposed, but was not the only cause He suspected the corpus luteum, although curettage frequently cured

Menorrhagia, or " flooding " that nevertheless kept within normal time-limits was essentially due to uterine " insufficiency," which might be the result of many diverse factors It was associated with chronic sub-involution and metritis with senility and with general debility, and might be due to any cause which lymphaticus" type In Dr Timme's opinion, ophthalmoplegic migraine was essentially pituitary in origin, the enlarged pituitary impinged upon the cavernous sinus and thus involved the oculomotor nerves

Dr **GORDON HOLMES** (London) regarded migraine as a definite clinical entity, although other conditions might give rise to attacks resembling migraine Visual symptoms were by no means a constant feature of the disorder, and consequently many undoubted cases were not recognised As regards the vascular hypothesis, physiological evidence lent no support to the presence of a vasomotor mechanism, nor of sympathetic innervation, in the cerebral or meningeal vessels Also, the onset of the symptoms in migraine were, in his opinion, too rapid to be accounted for by pituitary hyperplasia It was known that the brain was sometimes subject to localised swellings; further, that in certain instances of decompressive operations performed for gunshot wounds, &c, on migrainous subjects, the migraine had disappeared after the operation Further observation was necessary on these points Finally, Dr. Holmes referred to the condition known as migrainous neuralgia

Dr **R G GORDON** (Bath) considered that in sufferers from migraine there was an underlying psychological condition that had many analogies to that of epilepsy There was the same narrow outlook and truculence towards certain things—a compensation for a feeling of inferiority This fact was fully borne out by psychological investigation Both conditions probably consisted in an interference with, or paralysis of, higher cortical centres with a consequent release of lower centres Slight traumata of the occipital cortex had been known to give rise to what might be termed traumatic migraine There were also rare cases in which migraine was followed by automatism similar to that of epilepsy, and Dr Gordon described a case in which the patient, following an attack of migraine, behaved in an asocial manner, threatening violence to members of his family, and recovering after an interval with no recollection of what he was doing during the automatic period

Dr **E I SPRIGGS** (Ruthin Castle) had classified the various types of headache coming under observation in a general private hospital Of 1219 cases, 89 had complained of headache, and in 57 this was the sole symptom Of 100 consecutive cases of headache, all severe, 36 were migrainous in type, but only 12 appeared to be examples of true migraine Migraine was often associated with definite physical disorder such as gall-stones or obstinate constipation, and upon relief of such a physical state the migraine might disappear Dr Spriggs cited cases to illustrate this contention

Dr **W A. POTTS** (Birmingham) described certain personal experiences with regard to migraine He considered that many cases of a migrainous type were associated with hypoglycæmia When such headaches occurred early in the morning, barley-sugar was an excellent remedy

Dr **G E NESBITT** (Dublin) considered that suggestion might play a large part in the onset of an attack of migraine, eliciting symptoms from a patient with migraine had been followed by an attack in the investigator. By an effort of concentration during an attack it was sometimes possible to maintain central vision, in spite of the absence of peripheral vision The two ætiological theories which appealed to him most were those relating to vasomotor disturbance and to the pituitary gland.

Mr **E W BREWERTON** (London) mentioned a case in which great relief had been obtained by rest, with the application of heat to the occipital region by means of an indiarubber hot-water bottle until the visual symptoms had disappeared Cold applications were then applied until the headache was relieved.

Dr. **C WORSTER-DROUGHT** (London) mentioned that, contrary to Prof Bramwell's experience, he had met several examples of migraine and epilepsy associated in the same patient, the epilepsy was usually of the petit mal type He could remember no case of migraine in which some error of refraction had not been present, at the same time, it could not be claimed that correction of the refractive error relieved all cases though some were undoubtedly benefited He also drew attention to the occurrence of dilatation of the pupil on the affected side during an attack of migraine This sign suggested sympathetic stimulation and harmonised with the vasomotor hypothesis Finally, as regards treatment for the prevention of attacks, in his experience the most successful remedy was luminal, gr. ½, taken twice or three times daily Large doses of calcium had been disappointing in his cases, although a few were relieved Intravenous injections of calcium had sometimes been successful, while endocrine substances and peptone therapy had given no very encouraging results.

THURSDAY, JULY 22ND

At the second meeting of the Section Dr **E MAPOTHER** (London) opened a discussion on

Manic-Depressive Psychosis

The range of the term manic-depressive psychosis, he said, was largely a matter of convention, there was no constant or specific cause for the disorder and no physical modifications recognisable during life or after death Under the heading manic-depressive psychosis were included cases of functional mental disorder which showed as their predominant feature one or other of a contrasting pair of anomalous types of reaction (1) melancholia or depressive reaction, and (2) manic reaction The two syndromes were deviations from the normal in opposite directions and were often seen at different times in the same patient He then dealt with the relation of manic-depressive psychosis to the psychoneuroses, in a large proportion of both groups of disorder the attack was related to mental stress and led to a morbid protraction of a condition that the circumstances of the stress would be expected to cause. Attacks of melancholia and mania often amounted to decontrol of tendencies which had only just been inhibited when the patient was at his best Dr. Mapother next described the clinical variations in the melancholic type of reaction—e g, agitation in the elderly, and stupor in the young It was customary to distinguish agitated and resistive forms, according to the type of psycho-motor reaction, but such distinctions were very unstable Morbid fear with insight had been picked out and labelled "anxiety neurosis," but the condition seemed to merge into other types of depression such as agitated melancholia As regards the pathology of manic-depressive psychosis, it was not known whether the primary change was within or outside the central nervous system, but some evidence was gradually being accumulated that there occurred certain physical changes which appeared primary and essential, among these were histological changes in the cortex cerebri, gonads, and pituitary gland, hæmoclastic crises, anomalous blood-sugar curves, and disorders of gastric secretion It was to be admitted, however, that such changes were common alike to manic-depressive psychosis and to dementia præcox, the difference being merely one of intensity Ætiologically, the essential cause seemed to be an innate and inherent susceptibility to the condition, while the *actual* exciting factor was often mental stress—bereavement, financial worry, illegitimate *pregnancy* At various times there had been three attempts to replace heredity as an ætiological factor: (1) Psycho-analytical theory, implying a deviation of development by infantile experiences (2) Endocrine *theory, that the disorder* depends upon endocrine disturbance It was true that manic-depressive psychosis might occur in association with Graves's disease, but this did not make it justifiable to apply the same reasoning to cases in which no endocrine disturbance was present (3) Theory of toxic absorption from septic foci in teeth, tonsils, or bowel, &c.

Prof. **SHAW**, in reply, said that chronic metritis and subinvolution were clinically indistinguishable, but the former term could not be dropped, as the condition might occur in nulliparous women He believed that Dr Adamson's schoolgirls owed their trouble purely to the nervous strain; they were generally working for examinations at that time He treated them by curettage, something to stimulate the uterine muscle, such as pituitary, and by taking them away from school The only real treatment for subinvolution was another pregnancy, but even then normal involution could not be guaranteed Some cases could be treated in the same way as the schoolgirls, and could often be tided over until the menopause approached, when it was better to get rid of the uterus He was rather afraid of radium, since no one could tell him how it acted, and so many cases were associated with old chronic pelvic lesions that he thought it just as well to remove the organ altogether. No form of treatment should be used until the possibility of insidious malignant disease had been excluded

Prof. **WHITEHOUSE**, in reply, said that Dr Eames's cases should be treated by inhibition of the thyroid by X rays These did less damage to the thyroid than to the ovary as they inhibited without destroying Curettage should be a diagnostic procedure always, and full menstrual details should be given to the pathologist with the specimen Pathologists had to be educated in the newest work on the endometrium

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

WEDNESDAY, JULY 21ST

The first meeting of this Section was held in conjunction with the Section of Ophthalmology, Dr E **FARQUHAR BUZZARD**, President of the Section of Neurology, being in the chair, when Prof **EDWIN BRAMWELL** (Edinburgh) opened a discussion on

Migraine

He began by describing the characteristic symptoms associated with an attack of migraine Headache, he said, was often the only symptom, and vomiting might occur without the occurrence of headache Migraine and epilepsy had many points in common, they were both paroxysmal and periodic, they usually occurred in early life, and there might be a family history of predisposition Following both conditions an aura might be present, as well as cumulative effects—i e, after a period of freedom a bout of severe attacks followed The attacks in both migraine and epilepsy were more liable to occur at the time of the monthly period and they sometimes ceased entirely during pregnancy. Occasionally one might be substituted for the other In spite of the analogies between the two conditions, however, Prof Bramwell maintained that the resemblance was merely superficial and that they were rarely met with in combination If migraine developed in middle life an underlying causative condition should always be suspected The predisposing factor in migraine appeared to be an inherent instability of the nervous system, while among exciting causes of an attack were intense mental concentration, fasting, eye-strain, tobacco, anxiety, and worry. Vascular disturbances were often observed, including pallor or flushing, hardening of the temporal artery, and alterations in the calibre of the retinal arteries In Prof. Bramwell's opinion the actual headache was the result of a release from spasm of the meningeal vessels, since the brain was insensitive, the pain must be referable to the meninges The prodromal symptoms could be accounted for by spasm of the meningeal vessels and the ensuing headache by their subsequent relaxation There had also been a tendency to attribute migraine to an error of metabolism, while such symptoms as low blood pressure, polyuria, brachycardia, and low blood-sugar had been said to suggest an endocrine factor Among other ætiological theories were congenital narrowing of the foramina of Monro, which varied from time to time, and temporary enlargement of the pituitary gland. Treatment was a difficult problem It was necessary that every case should be subjected to a full investigation, with consequent elimination of any exciting factors Among the promising forms of treatment were peptone therapy, luminal, bromides, and nitrates

Mr W H. **MACMULLEN** (London), in opening the discussion from the standpoint of the ophthalmologist, commented upon the various visual symptoms so frequently associated with attacks of migraine Visual disturbances were the commonest of the subjective sensory phenomena Although they varied, one feature was frequently present—namely, a loss of sight in part of the field of greater or less extent These scotomata might develop suddenly to their full extent, or might start at a small spot and gradually spread Other subjective symptoms were migrainous spectra, the most important feature of which was a zig-zag or angled character Sometimes a scotoma, with or without associated spectrum, extended across the middle line of the visual field Rarely there was a central scotoma, and cases of transient total loss of vision had been recorded, as a rule, however, the fixation point was not involved The scotomata of migraine usually lasted a short time only, but cases of more persistent hemianopia had been reported Mr MacMullen also referred to ophthalmoplegic migraine, in which, following an attack of migrainous headache, an ocular palsy occurred Many of these cases, however, had subsequently been shown to depend upon organic disease, such as tuberculous meningeal exudate or orbital periostitis The explanation of the ophthalmic symptoms was difficult, as different parts of the visual apparatus were affected in different cases Bilateral scotomata suggested a change above the chiasma—e g, in the visual cortex—with gradual spreading A localisation in the basal ganglia or geniculate bodies had also been suggested Among the changes in the fundus, either dilatation or constriction of the retinal arteries might be seen, but often there were no abnormal signs In one case during an attack Higgens found the retinal arteries reduced to mere threads with engorgement of the veins He agreed with Prof Bramwell that vasomotor changes appeared to be at the root of the phenomena, and referred to a case in which migraine replaced a previous urticaria; the migraine lasted for 15 years and with its cessation the urticaria recurred though with less intensity As regards the influence of eyestrain there existed diametrically opposed views Some writers stated that there was no connexion between the two, and correction of an error of refraction never cured migraine On the other hand, Hurst maintained that migraine was invariably due to eyestrain In Mr MacMullen's experience the common error was a mild degree of hypermetropic astigmatism, often with a slight degree of heterophoria After correction of the error many cases derived benefit and some, indeed, complete relief It was only by organised team-work, however, that it was possible to ascertain the various factors that underlay migraine

Dr W **TIMME** (New York) considered that migraine was merely a symptom of some underlying condition, hence the discrepancy in the views advanced regarding its ætiology Migraine might result from eyestrain or from other causes, just as a cough or epilepsy might be a symptom of a more profound pathological state He wished particularly to refer to migraine of pituitary origin. The thyroid gland had been shown to enlarge periodically, so why not the pituitary? If the sella turcica was small, such pituitary enlargement would give rise to migrainous headache. later results of such enlargement might be seen in X ray examination, the sella turcica showing erosion and thus accommodating itself to the enlarged pituitary A particular type of individual that was predisposed to this form of disorder was the "status seemed to be the administration of the active substance of the gland. It appeared, however, that intravenous or intraperitoneal injections gave no constant results, and the efficacy of oral administration was often very doubtful. In some cases of the adipose type, thyroid in moderate or large doses led to some improvement. When more urgent symptoms of compression by a pituitary tumour of neighbouring structures appeared, there were only two effective modes of treatment—surgery and radiology.

Mr. NORMAN DOTT (Edinburgh) said that tumours in the pituitary region might originate either above or below the diaphragma sellæ. X ray examination often indicated the differential diagnosis. In supra-sellar tumours there was erosion of the clinoid processes and a flattening of the sella turcica, while in sub-sellar tumours the sella turcica was enlarged and might be ballooned. The differential diagnosis was important from the standpoint of surgical treatment, the method of approach being different in each case. Pituitary adenomata were very rare before the age of 15, and comparatively rare before 25, while supra-sellar cysts were commoner in young subjects. As regards the surgical treatment of pituitary disorders, it was not justifiable to operate for purely glandular symptoms. Severe headache and progressive failure of vision, however, should lead to a serious consideration of the question of operation, while operation should be urged when the visual fields were progressively disappearing. In most cases total removal of the tumour was impossible and scarcely to be contemplated. Subsequent enlargement had to be reckoned with. The aim was to try to give the tumour room to grow downwards by removal of the floor of the sella turcica. The trans-sphenoidal method of approach traversed a potentially septic field, but the tumour itself constituted a barrier between the subarachnoid space and the sphenoidal sinus. The trans-sphenoidal route was the method of choice for pituitary adenomata. Supra-sellar tumours were often incapable of complete removal. Good access could be got from above, therefore the trans-frontal method was most advantageous, the tumour being approached from the right side. In cases of doubt, trans-frontal exploration was indicated.

Mr. M. L. HINE (London), from the ophthalmological standpoint, advocated the use of white test objects for taking visual fields in cases of pituitary disorders.

Dr. W. J. ADIE (London) amplified the relationship of the pituitary body to the vegetative centres in the hypothalamus region. Their close anatomical relationship suggested an equally close physiological connexion. He submitted that these vegetative centres and the pituitary body formed a physiological mechanism which might be termed the pituitary-'tween-brain system. The same symptoms and syndromes might arise from disease strictly confined either to the glandular or the nervous part of this system. It had been shown that minute lesions confined to the 'tween-brain and sparing the pituitary could cause glycosuria and polyuria and be followed by obesity and genital atrophy. Dr. Adie illustrated his remarks by reference to certain cases of encephalitis lethargica.

Dr. H. GARDINER-HILL (London) described cases of obesity and growth disturbances in children in which there was no evidence of pituitary tumour. In over 100 children with clinical features suggestive of pituitary disease and in whom carbohydrate metabolism was altered, he had found evidence of pituitary or supra-sellar tumour in only about 10 per cent., and these were cases of the true Fröhlich type. There was also a high proportion of cases in which obesity and overgrowth was combined with early development again without evidence of pituitary tumour. In these cases the obesity was often extreme at the age of 14 or 15; its onset was accompanied by marked acceleration of growth which continued until puberty when it ceased.

Mr. G. JEFFERSON (Manchester) dealt further with the question of surgical treatment. The supra-pituitary tumour or cyst was accessible only by the trans-frontal method of approach. As regards the true pituitary tumour, there was still a difference of opinion about the best method of attack; Mr. Jefferson favoured the trans-sphenoidal route. Entire removal of such a tumour could scarcely be hoped for; the operation was largely one of local decompression—to relieve visual defects or to prevent blindness. He then described in detail the trans-sphenoidal operation.

Dr. ELIZABETH EAVES (Sheffield) gave particulars of three cases of dyspituitarism examined post mortem. In the first, the pituitary gland was small and considerably fibrosed; in the second—a case of infantilism with polyuria—the whole brain showed hypertrophic sclerosis and the pituitary was compressed by a dense capsule. The third case was one of encephalitis lethargica in which the anterior pituitary lobe was fibrosed. Dr. Eaves showed sections of the pituitary glands of these cases and also described certain experiments she had carried out showing the effect of insulin upon the pituitary body.

Dr. C. G. IMRIE (Sheffield) gave details of a case of polyuria following encephalitis lethargica in which the symptom was controlled by pituitrin injections. The pituitrin was not necessarily specific, as J. S. B. Haldane had shown that pituitrin would control the polyuria following the taking of large quantities of water. When the percentage of blood-sugar was low the effect of pituitrin was to cause a rise of blood-sugar, rendering the curve more normal; indeed ½ c.cm. of pituitrin had a greater effect on the blood-sugar curve than 50 g. of glucose.

Reviews and Notices of Books.

PSYCHOLOGICAL MEDICINE.

A Manual on Mental Diseases for Practitioners and Students. Fourth edition. By Sir MAURICE CRAIG, C.B.E., M.D. Camb., F.R.C.P. Lond., late Physician for and Lecturer in Psychological Medicine, Guy's Hospital; and THOMAS BEATON, O.B.E., M.D., M.R.C.P. Lond., Senior Assistant Physician and Physician to Out-patients, Bethlem Royal Hospital. London: J. and A. Churchill. 1926. With 25 plates, some in colour. Pp. 437. 21s.

IT has been a pleasant and stimulating task to review the fourth edition of this well-known text-book. This is the first edition to appear under the joint authorship of Sir Maurice Craig and Dr. Beaton, and it may be confidently predicted that it will not be the last.

The book is divided into nine sections containing 26 chapters. Besides the usual subjects dealt with in a work of this sort there is a section on Mental Deficiency, and a final section on Miscellaneous Subjects contains chapters on malingering, case-taking, the legal relationships of insanity, treatment and laboratory work. The last is a welcome and much needed addition to works on psychiatry, and might be extended in future editions. It contains short accounts of the more important laboratory tests which are useful to the practising clinician in the investigation of his cases. It calls attention to the necessity for blood counts, blood-sugar estimations, and detailed examination of the urine and cerebro-spinal fluid, and it points out how much information can be gained from estimating basal metabolism and protein sensitivity. Such investigations are of great value in clearing up the cause of an obscure confusional state, and it is right to insist on their importance.

The sections on the Psychoses are admirable. The classification is clear and is well justified throughout. Ideas of classification are at present somewhat nebulous, and that adopted, which owes something to the influence of Kraepelin and Bleuler, may not agree with the views of some authorities, but it is certainly practical. Of special interest is the chapter

Further evidence was necessary before this latter view could be accepted, although it was true that syndromes of a manic-depressive type might result from febrile disturbances such as influenza If arterio-sclerosis could be excluded and there were no paranoid features present, recovery from the attack was possible even in involutionary forms The duration of a melancholic phase was seldom less than two or three months, while few cases of mania recovered before two or three weeks In the diagnosis of manic-depressive psychosis it was necessary to exclude organic diseases such as general paralysis, encephalitis, arterio-sclerosis, thyroid excess, and alcoholism Finally, Dr Mapother dealt briefly with the question of treatment In view of our deficient knowledge of the disorder, treatment was of necessity mainly symptomatic In acute mania home treatment was inadvisable In general, psychotherapy for these cases was of little value and might even be harmful, but temporary effects were possible in the early stages by persuasion, encouragement, and firmness. Treatment by means of thyroid, somnifen, and removal of septic foci had not been very encouraging With regard to hypnotics, Dr. Mapother agreed with Sir Maurice Craig that too serious a view was taken of the danger of habit-formation and too light a regard paid to the damage that might result from restlessness and insomnia

The President believed that in mild form manic-depressive psychosis was a more common disorder than generally supposed It was important to recognise it from the standpoint of both prognosis and treatment He disagreed with Dr Mapother on the question of anxiety neurosis being regarded as a subdivision of manic-depressive psychosis; he submitted that to distinguish between the two conditions was of fundamental importance as regards prognosis and treatment Manic-depressive cases were to be protected from suicide and from misjudged kindness in the form of psycho-analysis, they would recover at an uncertain date In anxiety neurosis the time of recovery depended upon the ease with which the cause of the anxiety could be disclosed, there was no fear of suicide and little fear of analysis.

Dr T A. Ross (Penshurst) joined issue with Dr Mapother on the question of the identification of psychoneuroses with manic-depressive psychosis The fundamental difference between the two conditions was one of mental state By careful attention to this factor differential diagnosis was possible Among essential differences between the two conditions was that of remorse No patient suffering from a psychoneurosis ever complained of remorse; if present, the case certainly belonged to the manic-depressive group The psychoneurotic always blamed something or somebody else for his disorder—never himself; further, even when apparently well, he was never really *quite* well—he was easily tired or upset On the other hand, the manic-depressive complains of no symptoms when free from his malady

Dr. R D Gillespie (London) considered that morbid dissatisfaction with oneself was the keynote of manic-depressive psychosis There was also an essential difference between the latter and psychoneuroses He reminded Dr. Mapother that the cortical and gonadal changes to which he had referred had not been fully confirmed Under the influence of Kraepelin, there had been an undue tendency to limit the conception of manic-depressive psychosis, possibly fresh divisions could be distinguished, such as reactive depression, psycho-neurotic depression

Dr. R H Cole (London) believed that everyone was liable to manic-depressive reactions of a mild type and that manic-depressive psychosis was merely an exaggeration of this state It was doubtful, however, if sufficient evidence existed for saying that a psychoneurosis could become a definite psychosis

Friday, July 23rd

At the third session of the Section Dr. Gordon Holmes opened a discussion on

Pituitary Disorders

In recent years, he said, the physiology of the pituitary gland had become a vexed question It might be said, however, that in general the pituitary was assumed to influence growth, metabolism, urinary secretion, and sexual function The clinical symptoms of pituitary disease were usually divided into those due to over-activity of a part of the gland and those resulting from loss or deficiency of some of its secretions This classification was probably the most useful that could be proposed in the present state of knowledge The best known and most common form of pathological overgrowth was acromegaly Dr Holmes then described the clinical features of this condition, illustrating his remarks with lantern slides of cases A little-known sign was enlargement of the intestines, especially of the colon The usual lesion responsible for acromegaly was an eosinophil adenoma of the anterior lobe Dr Holmes dealt with the various clinical types of pituitary deficiency such as the Fröhlich and Lorain type of hypopituitarism It should be remembered, he said, that adiposity might be due to atrophy of the suprarenal cortex in the absence of any pituitary disease Glycosuria often occurred in acromegaly and could be controlled by insulin injections, just as in diabetes On the other hand, in hypopituitary patients there was often a marked increase in carbohydrate tolerance, amounts larger than 150 g of glucose being necessary to produce glycosuria The investigation of the blood-sugar curve on the administration of glucose was a valuable diagnostic sign In pituitary deficiency the curve usually rose more slowly and remained raised for a longer period than normally The basal metabolic rate was also lowered in hypopituitary states and raised in acromegaly and giantism, but this was apparently not a constant rule Polyuria and diabetes insipidus had also been attributed to disease of the posterior lobe of the hypophysis Recent observations, however, have thrown doubt upon this explanation of polyuria, and many of them pointed strongly to the symptom being directly due to a lesion of the hypothalamus The temporary relief of diabetes insipidus by pituitrin, however, suggested that the pituitary gland might play a part in its production In cases of pituitary tumour both the systolic and diastolic blood pressure were usually lower than normal Dr Holmes next discussed pressure symptoms resulting from an enlarged pituitary, and showed lantern slides of different types of visual field disturbance in cases of tumour of the organ. Among other pressure symptoms, diplopia, strabismus, ptosis, and trigeminal pain might occur Papilloedema was rarely seen in simple pituitary tumour, but it occurred frequently with extra-sellar growths. Erdheim had first suggested that disturbance of the hypothalamus was the cause of many of the symptoms attributed to the pituitary, and Aschner and others had provided further experimental evidence in favour of this thesis It seemed to be definitely established that polyuria and temporary glycosuria could be produced by lesions of the tuber cinereum, and some experimenters claimed that adiposity and genital atrophy might result from injury of the base of the brain with the pituitary gland intact Diabetes and glycosuria had been found associated with lesions limited to the tuber cinereum; obesity had also been observed in disease of these parts The major clinical manifestations of pituitary disease were not common, but it was probable that certain minor disturbances of health, which often escaped notice, were the result of pituitary disturbance; unnatural obesity, stunted growth, and sexual weakness, for instance, might be of this origin, though accompanied by no other evidence of pituitary disease As regards treatment in hypopituitarism, the most rational procedure much explanatory description In most cases one or two lines suffice and succeed in conveying the essential features of the histology In the very complete chapter on syphilis (95 pages) there are five illustrations of the genital and no less than 12 of extragenital chancres This chapter alone, with its colossal bibliography of five and a half pages in small print, renders the whole volume noteworthy The writer's industry and acquaintance with the literature are exemplified by a brief running commentary to many of his references—e g, "an important and valuable contribution on syphilis of the nervous system," "exhaustive original studies on absorption of mercurial inunctions" This original treatment of the bibliography will save intending authors a great deal of unnecessary reading and reference The method of classification is not altogether satisfactory, and it is difficult to understand why epidermolysis bullosa, which is a congenital affection, is placed in the "inflammatory group," while the tuberculous and syphilitic diseases of the skin find a place among the "new growths" In this section, too, there is a grave omission English dermatologists are in agreement on the great importance of Schaumann's work on the type of "tubercular sarcoid," to which he has given the name of 'benign lymphogranuloma' The first of his papers was published in 1914, and he read a much appreciated paper on the whole subject before the Dermatological Section of the Royal Society of Medicine in December, 1924 But no reference can be found to it in this book His geographical situation has afforded Prof. Sutton extensive experience of such relatively rare conditions as blastomycosis, espundia, yaws, sporotrichosis, and mycetoma, all of which are illustrated by actual photographs The chapter on leprosy, too, could only have been compiled by a writer with exceptional facilities, while those on tuberculosis and the tuberculides will repay a detailed study

The subject of treatment is briefly summarised, and the author has been careful to avoid the error of submitting a large and confused catalogue of alleged remedies from which the inexperienced practitioner is left to make a selection He has also skilfully avoided the equally undesirable fault of dogmatism Regarded from the point of view of a work of reference this text-book is fully the equal of any in the English language, and probably more complete than any in the matter of illustrations It should find a place on the shelves of every serious student of dermatology

PRACTICE OF UROLOGY.

By HUGH H YOUNG and DAVID M DAVIS With the collaboration of FRANKLIN P JOHNSON In two volumes London W B Saunders Company, Ltd 1926 Pp 1433 £5 5s.

THIS large treatise is based on a study of 12,500 urological cases and the work has been well done, the peculiar value of the book lying in the personal note that permeates it throughout Mature judgment resulting from an immense individual experience is handed out to the reader and no mere compilation of the literature The preparation of the book must have necessitated the reading through of thousands of case-histories, the writing of innumerable letters of inquiry, and countless clinical examinations of patients long since discharged from the clinic. This method of writing, however, leads to certain omissions For instance, less attention is devoted to suprapubic prostatectomy than its generally recognised importance deserves There is no account of exposure of the lower ends of the ureters by a median subumbilical extraperitoneal route But it is open to question whether these omissions are a drawback It is of more advantage to listen to what Young has to say about perineal prostatectomy than to read his account of the suprapubic operation, which is only done in his clinic for some special reason as, for instance, when there is an accompanying ankylosis of the hip-joint or when a perineal operation has been done already, or when, in attempting it, a laceration of the rectum or urethra has occurred Young has performed 1049 perineal prostatectomies with a mortality of 3 4 per cent—a truly wonderful achievement The mortality in 108 suprapubic operations was 8 2 per cent With regard to radical extirpation of the malignant prostate, in the later cases it has been possible to do this without injury to the external sphincter The results have proved to be ultimately somewhat better than those following radical operation for carcinoma of the breast

There is so much information to be gleaned from these two volumes that it is difficult to select sections for special mention or commendation Noteworthy are the accounts of the radical cure of incontinence, the removal of bladder diverticula by suction, and the surgical treatment of tuberculous epididymitis When there is a stone in the ureter the author does not counsel a long expectant policy, advice which would seem to be sound from all points of view There were curiously few plastic operations for hydronephrosis performed considering the large number of cases under review Of five patients treated in this way, only four could be followed up, and in three of them cure resulted The description of the physiology of urination, of the phenolsulphonephthalein test of renal function, and of the decompression apparatus used in the clinic make interesting reading

---

NOTABLE BRITISH TRIALS

Trial of Katharine Nairn Edited by WILLIAM ROUGHEAD London and Edinburgh W Hodge and Co 1926. Pp 257 10*s* 6*d*

THE latest volume in the series of "Notable British Trials" deals with the famous proceedings against Katharine Nairn on the charge of murdering her husband, Thomas Ogilvy, in 1765 Mr William Roughead, well known as a student and expositor of the criminal annals of Scotland, edits the report, provides an admirable introduction, and prints certain fresh material which his research has discovered. The case is of strong medico-legal interest, an early instance of arsenical poisoning The charge would nowadays be proved or disproved beyond doubt by expert scientific evidence But, though the dead man's symptoms before death and the outward appearance of his body after death were described by witnesses, there was no post-mortem examination Doctors gave evidence, but they mostly disclaimed experience of deaths due to poisoning, the chief expert testimony was that of an Edinburgh surgeon, who had the advantage of having once attended a woman who was believed to have died of arsenic Mr Roughead has much enhanced the value of his volume by including a note by Prof. Harvey Littlejohn upon the medico-legal aspects of the trial wherein the medical symptoms are summarised and the inferences to be drawn therefrom are stated

Katharine Nairn, daughter of a Perthshire baronet, married Thomas Ogilvy in January, 1765, when she was a girl of 19 He was twice her age, and apparently in indifferent health His brother, Lieut. Patrick Ogilvy, invalided home from abroad, joined the household, and it was thought that he and his sister-in-law grew overfond of one another The brothers quarrelled and Patrick left the house At the end of May he bought a small phial of laudanum and about an ounce of arsenic, ostensibly to destroy some dogs. On June 5th a messenger from Patrick brought a packet to Katharine Next morning, Thomas the husband, kept his bed, having been unwell in the night Katharine was seen to make him a bowl of tea and to add sugar and milk This she took upstairs to him Soon afterwards he was taken very ill and complained of having been poisoned Presently he rose, dressed himself and went out, but soon he was back in his kitchen where he was violently sick At midnight, before the arrival of the doctor who had been summoned, he died Five days later three doctors were assembled for a post-mortem on adolescent psychoses, dementia præcox, and dementia paranoides These conditions are described in a masterly manner, and this chapter, more than any other, gives the authors a chance of aptly presenting the biological views of mental disorder which they hold The known pathology of these conditions is fully discussed and illustrated by many excellent plates—amongst which, however, it is surely a mistake to include one which shows sections cut from the brain of a patient with dementia præcox whose death was caused by pneumonia, since no reliable conclusions can be drawn when an acute infective condition obscures the picture

That part of the book devoted to general paralysis and other syphilitic infections of the nervous system is also well illustrated The authors have a cautious attitude towards the malarial treatment of paresis, and do not go into details about the way in which it is carried out, which is perhaps wise, for the treatment requires most careful handling; what would be useful to the practitioner would be a short paragraph giving the contra-indications to the use of malaria in treating a paretic; age, for example, is a most important factor, while remission is most likely to occur in the early stages, as Dr C P Symonds points out in THE LANCET Extra Number on "Early Mental Disease"

Alcoholic mental states are graphically described and the lines of treatment well presented, but little or nothing is said about the psychological factors which underlie drinking These have been carefully studied by a number of observers and deserve some mention. The student nowadays is not content to read that a case of delirium tremens suffers from zoological hallucinations He wants some explanation as to why these hallucinations are nearly always of "animals and insects that crawl about his bed," and he wants also some explanation of the mechanisms which determine the habit of drinking to excess These remarks naturally introduce the subject of psycho-analysis and the modern concept of the unconscious mind The authors describe psycho-analysis in a brief paragraph, which concludes with the statement that "it is very doubtful whether psycho-analysis provides either an explanation or a remedy for all psychological phenomena" The sentence summarises the attitude of the authors to psycho-analysis The section on Psychology at the commencement of the volume is concise, and is no mere reproduction of other writers It is well and forcefully written and can be understood with readiness by the student. The same remarks apply to the chapter on symptomatology, but in both more attention might have been paid to modern psycho-pathology. Practitioners of the analytic schools will quarrel with the view that the procedure consists of explaining the theory of analysis to the patient, and Freudians are not likely to accept as a fair presentation of their views the statement, on p 263, that anxiety states result from the *cessation* of coitus interruptus

The psychoneuroses and neuroses are very ably dealt with, though here again the psycho-pathology of the conditions is not very fully explained But what is important is the fact that Sir Maurice Craig and Dr Beaton evidently regard these minor mental maladies as in no way sharply divided from the graver disorders of mind There has been a tendency to divorce these common mental states from the severer grades of mental illness The term neurasthenia is discarded; the authors consider that most so-called neurasthenics are constitutional depressives with hypochondriacal developments the rest belonging to the anxiety or obsessional groups

Much has been done in this work to draw together psychiatry and general medicine The biological meaning of symptoms in states of insanity, of whatever degree of severity, is strongly insisted upon The reader feels that every page is the result of clinical experience, of long and intimate contact with patients The book is not an arm-chair product, but is alive with practical experience and the original presentation of old problems

AURICULAR FIBRILLATION.

By J G EMANUEL, B Sc, M D, F R C P, Physician to the Queen's Hospital, Birmingham Birmingham: Cornish Brothers, Ltd 1926 Pp 31

THIS small volume contains the two Ingleby lectures delivered at the University of Birmingham in 1925 The text is well illustrated by electrocardiograms and charts, and the clinical aspect of the subject is thoughtfully considered In such limited compass it is not possible to deal comprehensively with auricular fibrillation, and the author has accordingly confined his attention to certain features illustrated by clinical cases under his own care Special stress is laid on the part played by toxins, not merely in causing fibrillation, but also in producing an impairment of conductivity in the Purkinje system which results in a relative bradycardia The effect of digitalis on fibrillation and normal rhythm respectively is well illustrated by a case of paroxysmal auricular fibrillation During the paroxysms the ventricular rate was in the neighbourhood of 90 per minute, the patient being well under the influence of digitalis, but on reversion to normal rhythm it rose to 120 or 140 per minute, to return again to 90 as soon as another paroxysm supervened Dr Emanuel suggests that the potent action of digitalis in fibrillation is attributable to the abnormal nature of the impulse, and he expresses the further opinion that the ventricle will contract with the maximum efficiency only in response to an impulse arising in the sino-auricular node This is a somewhat daring hypothesis, for the cardiac impulse is generally held to be similar in nature to the nervous impulse which is known to obey the "all or none" law In another case the site of action of digitalis was studied by repeated subcutaneous injections of atropine. At first atropine produced a quickening in the ventricular rate of about 50 beats per minute, but when the patient was fully digitalised the acceleration only amounted to 10 to 15 beats per minute, suggesting that the early digitalis effect was due to vagal stimulation, while the later effect depended on a direct action on the cardiac muscle For rapid digitalisation the author employs Nativelle's granules, as many as nine of the larger granules (1/240 gr), each of which he considers is equivalent to 30 minims of the tincture, being given in 24 hours A final section deals with quinidine treatment, and stress is laid on the importance of giving the drug at two-hourly intervals

The volume will be read with interest by those who follow the more recent advances in cardiology

---

DISEASES OF THE SKIN

Sixth edition By RICHARD L SUTTON, M D, LL D, F R S Edin, Professor of Diseases of the Skin, University of Kansas School of Medicine London: Henry Kimpton. 1926 Pp 1303 52s 6d

AN ideal text-book on skin diseases can be compiled only by a teacher of experience, energy, and a certain leisure The text should be as free from hypothesis and theoretical argument as is compatible with the intricacy of the subject It must be profusely and accurately illustrated by photographs and coloured sketches of the actual lesions, of which, if possible, more than one type should be represented and amplified by at least two microphotographs—a low and a high power magnification—of typical sections It must be up to date and provide a bibliography which should be cosmopolitan and not national only Finally, the index should be complete

The majority of these desiderata are fully met in the latest edition of Prof Sutton's admirable work, which first appeared in 1916 There are 1158 illustrations in 1268 pages of text—almost one to the page The value of these in enlivening the text, reviving the visual memory of similar cases, and for purposes of comparison can scarcely be exaggerated The excellent microphotographs are not spoiled by too

ears that
pathogenic bacillary infection the former usually are the *B typhosus* and the *B paratyphosus* B inhabiting both intestines and biliary system, the latter several allied strains of *B. flexner* inhabiting the large intestine chiefly. Both motile and non-motile infections may occur at different times in the same individual, and when pathogenic organisms are prevalent certain lowly- or non-pathogenic organisms—e g , *B morgan* No 1—are commonly also found There is considerable evidence in favour of individual susceptibility to these infections *B typhosus* and *B. paratyphosus* B, when they occur, are as a rule readily controlled by systematic clinico-bacteriological methods, since only actual cases or inoculated persons provide a Widal reaction, and systematic blood examination and segregation of all cases of illness will ensure isolation of the infected patients, the diagnosis being confirmed by bacteriological study of the excreta The only difficulty likely to be encountered is the possible existence of a non-agglutinating carrier Such are, however, fortunately very rare, though their occasional existence seems to be definitely proved. Whether removal of the gall-bladder will permanently cure these cases remains yet uncertain It must not be forgotten that at any time a case of typhoid or para-B may be introduced from outside by either staff or visitors, and this is a probable cause of sporadic cases. The Flexner bacillus is a much commoner infection, due to the fact that even an isolated case of clinical dysentery is invariably accompanied by a number of positively agglutinating cases, which may be the result of infection or merely of ingestion Extensive measures of isolation are therefore required whenever active cases are discovered, since delay for the repeated systematic examination of fæces is likely to result in the appearance of further actual cases or even of a definite epidemic It is well known that wholesale transfers of patients and the opening of new asylums are apt to be followed by epidemics of enteric infection. This result is due to the fact that the relative immunity to its own strain acquired by an asylum population does not extend to any foreign strain introduced Amongst batches of untested transfers, however otherwise carefully these may have been selected, a number of positively agglutinating (non-inoculated) cases may be found, and some at any rate of these, unless isolated, will infect the strange population into which they are introduced. A certain percentage of new admissions, and also—which may seem strange—a certain percentage of (non-inoculated) probationer nurses may be found to be positively agglutinating The former require isolation and investigation and the services of the latter after confirmation of the test should be dispensed with Finally, it is of the greatest importance that a post-mortem investigation, including the systematic examination of and the taking of cultures from the intestine, should be performed in the case of every death occurring in a mental hospital

Inoculation with autogenous vaccines in selected cases of dysentery is a valuable means of treatment and it has certainly done no harm when pressed in confirmed cases of para-B and typhoid In the former cure has sometimes followed the pushing of inoculation to the danger point. The question of preventive inoculation is important, an interesting illustration of its application is given in the article by Dr C A Hogg and Dr O Latham, which appears in this issue of The Lancet If a population is known to be free from enteric infection, inoculation against infection of a certain kind is undoubtedly highly protective for a fairly long period On the other hand, unless entire freedom from the particular examination The body was not opened, however, it being thought that its state of putrefaction was such that no signs of the cause of death would be discovered Katharine and Patrick were jointly indicted not only for murder but also for incest They were found guilty on both charges Patrick was hanged, protesting his innocence, but Katharine obtained a temporary respite by saying she was pregnant. She was thereupon examined, not, as under the English custom, by a jury of matrons, but by five midwives, who a few months later confirmed her statement. On Feb 26th, 1766, her child was born, on March 17th, when the judges reassembled in the Tolbooth to pronounce her doom, it was found that she had escaped from prison She fled to France, where she met with further romantic adventures, finally ending her days in a convent

Were the prisoners rightly convicted? The evidence of incest was far from overwhelming, the murder charge rested mainly on the behaviour of the parties and on Patrick's purchase of arsenic This purchase he had not to explain in those more merciful days when prisoners had not the doubtful privilege of going into the witness-box Katharine was of decent upbringing and had married her husband, against her family's wishes, apparently for love Why should she so soon have turned against him? If she and Patrick were lovers, they could not have married even when Thomas was put out of the way It was a strange case with strange witnesses and strange evidence Readers of the story so well put before us by Mr Roughead will be able to form their own conclusions

MODERN METHODS OF AMPUTATION

By THOMAS G ORR, A B., M D, F A.C S, Professor of Surgery, University of Kansas London. Henry Kimpton. 1926 With 104 figures Pp 117 16s.

IN a concise form Prof Orr gives directions, illustrated by clear figures, of the more usual amputations There is little discussion in his book of the pros and cons of the various procedures, and the details given are somewhat scanty For instance, in describing Syme's amputation the author does not mention some of the mistakes into which the careless or inexperienced operator may fall These mistakes may seriously detract from the value of the stump which, in favourable circumstances, should be the best of all for locomotive purposes A little more precision as to the minimum length of bone which can be utilised in a thigh stump would have been useful to an operator not familiar with the possibilities of practical prosthetics In the chapter on cineplastic amputations, Prof Orr says that "very little of such surgery has been done in America or England" In this country a considerable number of such operations were performed during and after the war, but the practical results were so discouraging that the method may now be regarded as abandoned In Germany the enthusiastic Sauerbruch still claims success, the silence of other German surgeons on the subject is significant A chapter on artificial limbs concludes the work, but it was evidently not possible to do this subject full justice in the limited space devoted to it The paper, type, and illustrations are all admirable, and within its limitations this book should be useful

JOURNALS

JOURNAL OF INDUSTRIAL HYGIENE July, 1926—A definite and unique condition resulting from inhaling dust arising while mining iron ore in Cumberland is described from the clinical viewpoint by A. J. Cronin Certain tissue changes were found diffused through both lungs, associated with a clogged-up feeling and dyspnœa on exertion Chest expansion was limited; massive fibrosis and pleural involvement were absent No other evidence of pneumonoconiosis was present—The introduction of lead compounds into rubber for toughening purposes has for long been a source of plumbism C A Klein tells how the risk can be avoided by using special sheets containing 80 parts of lead to 20 of wax or rubber instead of a raw lead compound These sheets are made for the trade in bulk under special precautions—A careful comparative test of different instruments for determining air dustiness is described by S H Katz, G. W Smith, and W M Myers Equations are given for converting dustiness in terms of one instrument into terms of another The article is highly technical and mathematical—A research into the effect of turbulent air motion and of humidity on the stability of dust, *fume*, and *smoke clouds* is discussed by P Drinker, R M Thomson, and J L Finn Neither air motion nor humidity exerted any appreciable effect on silica dust, but both aided in clearing zinc oxide fumes, probably due to facilitating aggregation of particles

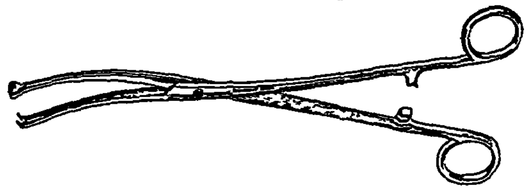
AN IMPROVED VULSELLUM FORCEPS

I HAVE had made a vulsellum forceps on the lines of a ring forceps My improved instrument does not tear out because it folds in a portion of tissue in the ring and the teeth do not catch when being inserted into the cervix, and the instrument does not tear out lacerations Scarifications are thus avoided

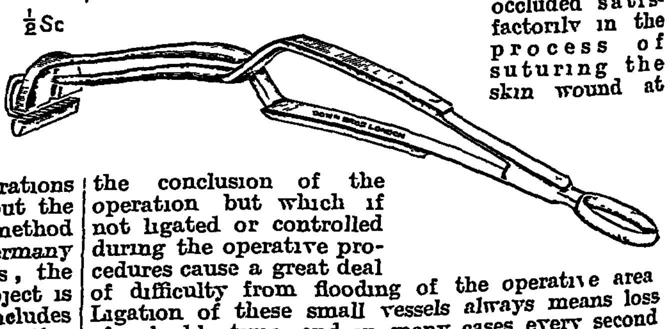


The manufacturers are Messrs C F Thackray, of Park-street, Leeds

Paisley H C DONALD, M B, F R C S Edin

HÆMOSTATIC FORCEPS

I HAVE devised a hæmostatic forceps (see figure) primarily for operations on the skull but also for all cases where a long skin incision is necessary There are always numerous small vessels which can be occluded satisfactorily in the process of suturing the skin wound at the conclusion of the operation but which if not ligated or controlled during the operative procedures cause a great deal of difficulty from flooding of the operative area Ligation of these small vessels always means loss of valuable time, and in many cases every second is of value



The chief advantages about these forceps are: ease of application, rapidity of application; they can be used on wound edges in place of towel-holding forceps, thus carrying out the double duty of (*a*) towel-holding forceps, (*b*) hæmostatic forceps (practically no Spencer Wells being required), the large area of the blades controls an extensive amount of cut skin edge (requiring fewer pairs), they can be quite well used for towel clips in the ordinary way in addition, and there are no screw-joints to rust or get out of order

Messrs Down Bros, Ltd, 21, St Thomas's-street, London, S E 1, are the manufacturers

ENTERIC INFECTIONS IN MENTAL HOSPITALS

THE publication of the Report of the Royal Commission on Lunacy has focused public attention on the difficulties in the administration of mental hospitals, of which none is greater than the prevention and treatment of enteric infections. These diseases have been largely eradicated by modern public health measures both from the population at large and from prisons and Poor-law institutions, and during the war preventive inoculation minimised their incidence amongst the combatants in spite of the necessarily bad hygienic conditions of stationary warfare. In mental hospitals, however, enteric infections have retained an undesirable prevalence, although recent research is at last making it possible to control or even to eradicate them. Enteric infections, then common in the general population, appeared in public asylums from their very inception. At Wakefield, built for 150 patients, a case of "bloody flux" arose within a week of the opening of the institution in 1818. Ten years later among the 256 patients the cases of dysentery became so numerous as to make it necessary to disperse the patients belonging to one of the wards into different parts of the house in order to turn that ward into an infirmary, where the dysenteric patients were kept distinct from the rest. Notwithstanding all that was done, fresh cases daily occurred, until, in the words of the medical director, a change took place in the weather, accompanied with the autumnal gales of wind. But meanwhile 14 patients out of 55 attacked in the course of the year died of the disease. In his report for the year 1831, referring to the alleged prevalence of dysentery in the asylum, the medical director states:

> "During a very hot summer and an unhealthy season subsequent to it, while the disease was both prevalent and fatal in the neighbouring towns and villages, my own and only child, a healthy boy of 3 years old, who fell a victim to it, was the only serious case in the institution. Lately a few cases have occurred, and four emaciated patients, two of whom were already sinking when attacked, have died from it. One case of dysentery now exists in the house; with this exception the inmates in general are in a very healthy state."

Nevertheless, as the years rolled on these diseases came to be regarded as a necessary infliction, and, under the general term "colitis," were thought to be one of the consequences of mental disease. It is not surprising, therefore, that MOTT and DURHAM, in their classical report published at the end of last century, whilst they stated definitely that "colitis" was in reality bacillary dysentery, nevertheless, on the information at their disposal, remarked that the disease rarely or never attacked the staffs of asylums. This valuable report did not obtain ready acceptance, since BEVAN LEWIS, as lately as 1909, lauded the systematic exhibition of "white mixture," a prophylactic treatment adopted by him in 1903.

For many years now systematic clinico bacteriological research has been carried out at various mental hospitals, including Wakefield, and reported to the Board of Control. From this it appears that of the motile and non-motile types of pathogenic bacillary infection the former usually are the *B. typhosus* and the *B. paratyphosus* B inhabiting both intestines and biliary system, the latter several allied strains of *B. flexner* inhabiting the large intestine chiefly. Both motile and non-motile infections may occur at different times in the same individual, and when pathogenic organisms are prevalent certain lowly- or non-pathogenic organisms—e.g., *B. morgan* No. 1—are commonly also found. There is considerable evidence in favour of individual susceptibility to these infections. *B. typhosus* and *B. paratyphosus* B, when they occur, are as a rule readily controlled by systematic clinico-bacteriological methods, since only actual cases or inoculated persons provide a Widal reaction, and systematic blood examination and segregation of all cases of illness will ensure isolation of the infected patients, the diagnosis being confirmed by bacteriological study of the excreta. The only difficulty likely to be encountered is the possible existence of a non-agglutinating carrier. Such are, however, fortunately very rare, though their occasional existence seems to be definitely proved. Whether removal of the gall-bladder will permanently cure these cases remains yet uncertain. It must not be forgotten that at any time a case of typhoid or para-B may be introduced from outside by either staff or visitors, and this is a probable cause of sporadic cases. The Flexner bacillus is a much commoner infection, due to the fact that even an isolated case of clinical dysentery is invariably accompanied by a number of positively agglutinating cases, which may be the result of infection or merely of ingestion. Extensive measures of isolation are therefore required whenever active cases are discovered, since delay for the repeated systematic examination of fæces is likely to result in the appearance of further actual cases or even of a definite epidemic. It is well known that wholesale transfers of patients and the opening of new asylums are apt to be followed by epidemics of enteric infection. This result is due to the fact that the relative immunity to its own strain acquired by an asylum population does not extend to any foreign strain introduced. Amongst batches of untested transfers, however otherwise carefully these may have been selected, a number of positively agglutinating (non-inoculated) cases may be found, and some at any rate of these, unless isolated, will infect the strange population into which they are introduced. A certain percentage of new admissions, and also—which may seem strange—a certain percentage of (non-inoculated) probationer nurses may be found to be positively agglutinating. The former require isolation and investigation and the services of the latter after confirmation of the test should be dispensed with. Finally, it is of the greatest importance that a post-mortem investigation, including the systematic examination of and the taking of cultures from the intestine, should be performed in the case of every death occurring in a mental hospital.

Inoculation with autogenous vaccines in selected cases of dysentery is a valuable means of treatment, and it has certainly done no harm when pressed in confirmed cases of para-B and typhoid. In the former cure has sometimes followed the pushing of inoculation to the danger point. The question of preventive inoculation is important; an interesting illustration of its application is given in the article by Dr. C. A. HOGG and Dr. O. LATHAM, which appears in this issue of THE LANCET. If a population is known to be free from enteric infection, inoculation against infection of a certain kind is undoubtedly highly protective for a fairly long period. On the other hand, unless entire freedom from the particular examination The body was not opened, however, it being thought that its state of putrefaction was such that no signs of the cause of death would be discovered Katharine and Patrick were jointly indicted not only for murder but also for incest They were found guilty on both charges Patrick was hanged, protesting his innocence, but Katharine obtained a temporary respite by saying she was pregnant. She was thereupon examined, not, as under the English custom, by a jury of matrons, but by five midwives, who a few months later confirmed her statement On Feb 26th, 1766, her child was born, on March 17th, when the judges reassembled in the Tolbooth to pronounce her doom, it was found that she had escaped from prison She fled to France, where she met with further romantic adventures, finally ending her days in a convent

Were the prisoners rightly convicted? The evidence of incest was far from overwhelming, the murder charge rested mainly on the behaviour of the parties and on Patrick's purchase of arsenic This purchase he had not to explain in those more merciful days when prisoners had not the doubtful privilege of going into the witness-box Katharine was of decent upbringing and had married her husband, against her family's wishes, apparently for love Why should she so soon have turned against him? If she and Patrick were lovers, they could not have married even when Thomas was put out of the way It was a strange case with strange witnesses and strange evidence Readers of the story so well put before us by Mr. Roughead will be able to form their own conclusions

MODERN METHODS OF AMPUTATION.

By THOMAS G ORR, A B, M D., F A C S, Professor of Surgery, University of Kansas London. Henry Kimpton. 1926. With 104 figures Pp 117 16s

IN a concise form Prof Orr gives directions, illustrated by clear figures, of the more usual amputations There is little discussion in his book of the pros and cons of the various procedures, and the details given are somewhat scanty For instance, in describing Syme's amputation the author does not mention some of the mistakes into which the careless or inexperienced operator may fall These mistakes may seriously detract from the value of the stump which, in favourable circumstances, should be the best of all for locomotive purposes A little more precision as to the minimum length of bone which can be utilised in a thigh stump would have been useful to an operator not familiar with the possibilities of practical prosthetics In the chapter on cineplastic amputations, Prof Orr says that "very little of such surgery has been done in America or England" In this country a considerable number of such operations were performed during and after the war, but the practical results were so discouraging that the method may now be regarded as abandoned In Germany the enthusiastic Sauerbruch still claims success, the silence of other German surgeons on the subject is significant A chapter on artificial limbs concludes the work, but it was evidently not possible to do this subject full justice in the limited space devoted to it The paper, type, and illustrations are all admirable, and within its limitations this book should be useful

matters of congratulation are the reorganisation by Dr J. E McCARTNEY, appointed director last year, of the pathological services of the various hospitals which are now to be grouped into two central laboratories, that of the Northern Group being completed two months ago. At the Queen Mary's Hospital for Children an experimental unit has been started to deal with 36 girls and 24 boys suffering from rheumatic fever, acute endocarditis, or chorea, research work being now in progress At the Downs Hospital for Children an artificial sunlight room has been fitted up for the treatment of children suffering from ear disease, rickets, and debility. A veranda has been added to the infirmary at White Oak for the use of children suffering from interstitial keratitis The revised dietary scale for children, which substituted butter for part of the margarine allowance, has been in operation for a year and is confirmed. These are a sample of the ever progressive activities of the Board's medical staff, of which examples will be given later at greater length

◆

MENORRHAGIA.

EXCESSIVE bleeding at the menstrual periods is a very common symptom, yet it is one for which, as often as not, no really satisfactory explanation can be found. Even the recognition of abnormal menstrual loss has its difficulties, for what is harmless and natural in one woman may give rise to general ill-health in another Often, of course, an excessive flow is associated with gross organic lesions of the generative organs, such as fibromyomata of the uterus, and here the accepted mechanical explanation appears adequate There remains, however, a large majority of cases in which no gross physical change can be detected, and it was these especially that came up for discussion at the Meeting of the Section of Obstetrics of the British Medical Association which we report on page 378 Amongst them perhaps the most interesting are the two forms of menorrhagia which occur, respectively, at puberty and in the second half of the child-bearing period In the last few years evidence has gradually accumulated that menorrhagia of this kind is not due to abnormality of the uterus itself or of its lining mucous membrane, but rather to an excessive stimulus to menstruation which acts upon them Unfortunately, the nature of the normal physiological stimulus to menstruation is not yet fully understood. Presumably a chemical hormone is the immediate agent, and the balance of evidence favours the view that this hormone is formed in the Graafian follicle, though the corpus luteum and the interstitial cells of the ovary are both possible sources; it seems clear, too, that the other ductless glands, particularly the thyroid and pituitary, have an important relation to the process

Soon after puberty there appear examples of hypo- and hyper secretion, recognised clinically as primary amenorrhœa and menorrhagia of puberty, which are comparable to the cretinism and hyperthyroidism due to abnormal function of the thyroid gland On this analogy very severe puberal menorrhagia might be treated by removing part of the ovary, though it is questionable whether the results would be better than those of partial thyroidectomy for hyperthyroidism, but, fortunately, nearly all cases of menorrhagia in young girls get better spontaneously, their cure often being hastened if calcium is administered, apparently because the metabolism of calcium is rather intimately related to menstruation Primary amenorrhœa is of special interest because its treatment may throw light on the mechanism of normal menstruation It is by no means a rare condition, but the published results of particular forms of treatment are very variable Sometimes the administration of thyroid and anterior pituitary extracts seems to have established menstruation—cases were recently reported in our columns by Dr H GARDINER-HILL and Dr. J. FOREST SMITH[1]—but usually it has failed. An occasional success has also been recorded with various ovarian extracts It seems possible that in some patients the ovary only needs a slight stimulus from the thyroid or pituitary to establish its secretory function, but where this function is wholly wanting the only hope lies in regular injection of the appropriate ovarian extract Unfortunately, no satisfactory ovarian extract is at present available, doubtless the ovary supplies more than one substance, and possibly these are mutually antagonistic

The other and larger group of cases of menorrhagia—those which occur in the later part of the child-bearing period—is not so interesting from the physiological point of view, but clinically is of considerable importance In these women curettage often reveals a degree of hypertrophy of the endometrium which most pathologists consider to be definitely in excess of that found at any stage of the normal menstrual cycle, but at the age when this condition is found so many diseases may have left their mark on the genital organs that the problem is greatly complicated and probably no one explanation applies to all the cases So far as investigation is concerned, it seems to be most useful to assume that the ovary is at fault It is conceivable that anything which causes a thickening of its tunic may, by preventing rupture of the follicles, prolong the period during which ovarian secretion is absorbed, and a few interesting cases are recorded in which ovarian grafts became cystic and gave rise to severe menorrhagia because they were in a position where the follicles could not easily rupture Whatever the cause of the condition curettage is usually only of temporary benefit—at the Nottingham meeting Mr. COMYNS BERKELEY described it as the commonest and most hopeless operation for hæmorrhage—and in the last few years radium and X rays have been more and more employed as remedies The results, though variable, have on the whole been good in so far as the menorrhagia is concerned, but most patients are only cured by a dose so big as to cause sterility, and this risk should certainly not be run without profound consideration Radium is generally effective at first, but when it is used there is a tendency for bleeding to recur after an interval of months, though this is by no means common; X rays, on the other hand, may be some time in acting, but a successful result is likely to be permanent This suggests that radium has an effect on both endometrium and ovaries, whereas X rays act on the ovaries alone These methods are simple—perhaps too simple, they are relatively safe and their administration causes the patient very little inconvenience, but they cannot be considered altogether satisfactory, for the ideal of cure must always be the re-establishment of normal function. In this they fail, for sterility is the rule, and too often the symptom treated is replaced by the complex of the menopause Improvement in technique may lead to better results, but the very way in which X rays and radium act suggests difficulties, and a far more useful therapeutic agent would be the chemical inhibitor of menstruation The corpus luteum appears to produce such a substance, but efforts to extract it have so far failed[2] At infection exists, its presence becomes difficult to determine owing to the loss of the agglutination test, bacteriological examination of the fæces alone is a tedious and not very certain business Prevention by inoculation is good, but detection and isolation of infected cases followed often by cure is better Preventive inoculation, in fact, is a valuable weapon in the hands of expert clinico-bacteriological departments which understand its limitations and the disability it produces, but inoculation is a dangerous tool if employed as a royal road to the prevention of any disease in the absence of a clinico-bacteriological department It would appear that, whilst modern sanitary measures will continue to improve the general health of mental hospitals, an equivalent permanent decrease in the prevalence of enteric infections is unlikely until inter-hospital transference of patients is reduced to a minimum and complete separation of healthy from potentially dangerous cases is rendered possible by the provision in every mental hospital of an expert bacteriological department Until this is done certain dangerous enteric infections will necessarily remain latent and unrecognised, liable at any time to become epidemic in their incidence The New South Wales mental hospitals are fortunate in that so far, owing to their isolation and relative youth, they have only had to meet and control typhoid fever, one of the more definite and best-known varieties of enteric infection The rather alarming quotation with which the article by Drs Hogg and Latham commences need not be taken too seriously Dysentery, para-B, and typhoid can at any time become dangerously epidemic in mental hospitals in the absence of expert clinico-bacteriological methods of prevention and treatment, but, granted similar conditions, so can any infectious disease known to medicine

THE METROPOLITAN ASYLUMS BOARD.

The appearance in the month of August of the report of the Metropolitan Asylums Board[1] gives recurrent occasion for an attempt to visualise the work of this body which is remarkable as an instance of evolution Established in 1867 to provide asylum, in the old sense of sanctuary or retreat, for the sick, insane, and infirm from all parts of the metropolis, the burthen of the Board has increased year by year from the imposition of new duties, while the old have never been removed On the side of mental affliction, the large group of harmless Poor-law imbeciles was its first care, to which has been added, as time has gone on, the oversight of feeble-minded (though uncertified) Poor-law children, the charge of sane epileptics, in 1917 the care of cases certified under the Mental Deficiency Act and, quite recently, the responsibility for aged persons requiring institutional treatment owing to mental infirmity On the side of physical affliction, the original group of four infectious diseases, at first limited to Poor-law cases, was extended, owing to the removal by Parliament in 1883 of the penalty of civil disability, to all cases whatever their status, and further by the continual addition of fresh diseases made notifiable to the health authority, of which the most recent are ophthalmia neonatorum and zymotic enteritis The Board is now the central metropolitan authority for dealing with sick and convalescent children and with those who suffer from ophthalmia, ringworm, and interstitial keratitis It trains boys for service on the sea, maintains a far-reaching ambulance service, provides casual wards for destitute wayfarers and foundlings, with a hostel to assist men to regain employment, and implements a scheme for dealing with the homeless poor at night.

The Board to which this vast and almost bewildering task is allotted is composed of 73 members, 55 of whom are elected by metropolitan boards of guardians and the remainder nominated by the Ministry of Health Three of its members at present belong to the medical profession—namely, Dr Ethel Bentham, Sir D'Arcy Power, and Sir William Smith, the two first being nominees of the Ministry For the third time in six years the Board has had to consider its own abdication, for, in common with other guardians of the poor, it received in January last the circular letter from the Minister of Health proposing (in the case of London) to transfer all the work of the Board to the London County Council. As on previous occasions, the Board stoutly asserts the principle of independent existence, contending that the Council would find it impracticable to undertake, in addition to its present duties, the oversight of 145 institutions—accommodating 82,500 persons situated over an area extending from Lowestoft to Littlehampton and from Margate to Wokingham—without surrendering the close contact between work to be done and the public for whom it is done, which has been the policy of the Board The report emphasises once again the importance of a form of management which invokes the voluntary services of a large number of public representatives to supervise the various hospitals and institutions It has fears for the effect of restricting supervision to visitors appointed locally without effective powers or adequate representation, and still more the effect of a system of purely official management In urging this view the Board will, we believe, have the cordial support of a large body of thoughtful persons

During the year under review, while the work of the Board has increased in many directions, a small number of innovations deserve special mention For 15 years past puerperal fever has been admissible to M A B hospitals, and a year ago, acting on a suggestion in Dame Janet Campbell's report, it was decided to concentrate these patients in a smaller number of hospitals where they might have the benefit of skilled nursing and specialist care The Eastern, North-Western, and South-Western Hospitals were selected for this purpose, Mr J M Wyatt, assistant obstetric surgeon to St Thomas's Hospital, being appointed obstetric consultant, and the 50 beds allotted will no doubt be filled as soon as their availability becomes widely known The issue of the new regulations regarding puerperal pyrexia will help in this direction The lines of general and local treatment have been laid down, and it is greatly to be hoped that with the opportunities thus offered for research and treatment something may be done to mitigate the high mortality of puerperal infection where the blood is found to contain septic organisms A second innovation has been the allotment of 100 beds at the Northern Hospital for the observation of children between 3 and 16 years of age who have had an attack of lethargic encephalitis This post-encephalitic unit, which is under the care of Dr S A Kinnier Wilson, is now fully occupied, and even in the short time that has elapsed the transference of such patients from their homes to the atmosphere of the unit has proved highly beneficial The tiresome inversion of sleep rhythm has been surmounted and only one case so far has proved refractory The question of a small hospital unit within the section is now under consideration Other providing a double safeguard against possible neglect of the trifling inflammations which may get well in a day or two, but which may, on the other hand, go on to a frank ophthalmia when it will be the duty of the practitioner to acquaint the local medical officer of health. This information in its turn will reach the county officer. In the actual care of the children, the duties of the health visitor are likely to be supervisory only, except where nursing assistance is not otherwise available; the larger sanitary authorities are advised to employ specially trained ophthalmia nurses; in rural areas it may be found necessary to provide a special nurse or to remove the child to hospital for treatment. One of the difficulties of the problem has been the fact that midwives are sometimes reluctant to call in medical help inasmuch as the fee is recoverable later by the local supervising authority from the mother or her husband, who may retaliate on the midwife. Sanitary authorities are asked to consider whether they should not refrain in future from exercising this power of recovery. In London the suggested arrangements are similar except that the onus for supervision and treatment of the case rests on the borough medical officer, the County Council sending an inspector of midwives to the patient's home but not being concerned further with the conduct of the case. The new regulations, if faithfully carried out, should ensure in the future the early care of sore eyes in the newly born before the inflammation becomes of a serious character.

---

[1] Twenty-eighth Annual Report of the Metropolitan Asylums Board for 1925–26 To be obtained from the Office of the Board, Victoria Embankment, London, E C 4 5s

THE FACTORIES BILL

IN the first week of August the Government's Factories Bill was published as promised. It is intended that the various trades and industries concerned shall have an opportunity to examine it during the autumn, to reach some measure of agreement if possible upon disputed points, and to make representations to the Home Office upon points where modification or explanation is desired. Our Parliamentary correspondent summarised the main provisions of the Bill in THE LANCET last week, when we took occasion to indicate its general lines of policy without exhausting the medical questions raised. The Bill, it may be further stated, declares that women and young persons must not work more than 4½ hours without a break of half an hour for a meal; they must not work more than 10 hours a day or 48 hours a week, nor before 6 A.M., nor after 8 P.M. during the week or 2 P.M. on Saturdays. As a concession to employers who have urgent contracts to fulfil, 100 hours overtime is to be permitted in the year, provided that not more than six hours overtime is worked in one week. The continued employment of young persons under 16 in factories is to be subject to a medical certificate of fitness for such employment after examination by appointed doctors. District Councils are to be given some control of the conditions of home work. They can notify the occupier of a factory or any contractor employed by him that the place where home work is done is "injurious or dangerous to the health of the persons employed therein." The person thus notified is then liable to a penalty of £20 if he gives out any work to be done in that place unless he can satisfy the magistrates that the place is not in fact injurious or dangerous to health. Among other health provisions of the Bill are a general duty to keep factories clean and free from effluvia, and a requirement to wash or re-colour all ceilings and interior walls every 14 months. There are special directions as to the carrying away of injurious and offensive dust and noxious fumes. Factory inspectors will have power to prohibit underground workshops, and basement bakeries will be prohibited save where they already exist. Provision will be made against spitting. Welfare of workers will be promoted by requirements as to drinking water and as to seats for women. First-aid facilities must be furnished. Safety provisions include fire escapes, the fitting of steam boilers with valves and gauges to avoid explosions, and belt and rope equipment for persons who have to enter places where there is danger of being overpowered by fumes, unless adequate mask apparatus is used. The normal penalties under the Bill are limited to £20 fine or £5 a day for a continuing offence. Where death or injury occurs through the factory owner or occupier's neglect to comply with the new legislation, a fine of £100 may be inflicted, which may be applied by way of compensation. Though the Bill will not please everybody, there seems nothing which cannot be made acceptable by modification and a reasonable spirit of give and take. Politics hardly enter into its consideration, for the Bill is the result of the work of successive administrations, and no party could hold office without undertaking to improve and reform the present state of the law.

AN ENCYCLOPÆDIA OF NUTRITION.

CONTEMPLATION of the subject of nutrition brings to light in a surprising manner the number of different branches of science and literature with which it is intimately related. It may be that the catholicity of nutrition, in subserving the most fundamental function of plants and the most primitive instinct of animals, has as yet hardly received articulate recognition. The remarkable work which Prof. Mayerhofer, of Zagreb, and Prof. Pirquet, of Vienna, have now completed[1] cannot fail to arouse in the reader a recognition of the limitless applications of the subject, as well as a lively admiration for the amazing industry and enterprise of the authors. The work has appeared in five instalments and takes the form of a miniature encyclopædia, comprising articles of greatly varying length on almost every subject directly or indirectly related to the nutrition of man or beast. The student of history, anthropology, agriculture, zoology, medicine—to mention a few only—will find in it a wealth of information on his particular specialty. The form of the articles is admirable, space being well apportioned according to the relative interest of the subjects, and in general the shorter notices are examples of successful condensation. Among the articles of historical interest which appeared in the earlier instalments were those on cannibalism, fishery, and the nutrition of primitive races. The final volume includes an essay on the ancient history of nutrition written mainly from the ethnological point of view. An exhaustive article on vitamins deals with both the chemical and physiological characters of these bodies and their relative occurrence in various articles of diet. A notable feature of the book, which adds greatly to its usefulness, is an appendix in which is set out a full analysis of over 300 foodstuffs, with the caloric values of the principal constituents of each of them. Every well-equipped library will find a place among its works of reference for this original volume.

PROSTATECTOMY.

IN a recent lecture[2] at St. Bartholomew's Hospital Prof. Hugh Cabot described suprapubic prostatectomy as foolproof, and on this ground commended it to the occasional prostatic surgeon. He made it very plain, however, that uniform success in the treatment of enlarged prostate can only follow a clear understanding of the risks of operation and the management of every patient according to the individual problems he presents. Prostatectomy, as he pointed out, is unlike the ordinary clean surgical operation because, in addition to the insult of the operation itself, it involves the risk of upsetting the renal function and seriously infecting the urinary tract. The symptoms due to enlarged prostate are, generally speaking, those of obstruction; this obstruction may have been going on for years; the kidney has been working against more or less continuous back-pressure, and when the obstruction is removed the all discussions of uterine hæmorrhage the need for a standard nomenclature becomes evident The terms proposed by Prof BECKWITH WHITEHOUSE were generally approved at the Nottingham meeting, and we take this opportunity of drawing attention to them.

Annotations.

"Ne quid nimis."

THE CINEMA AND THE CHILD

IN his annual report to the County Borough of Croydon Dr H P Newsholme makes some important suggestions concerning the influence of the cinema upon character formation in the child Hitherto this influence has been considered as affecting the conscious mind of the child, but Dr Newsholme believes that the circumstances in which the film is seen—the darkness, the quiet, the sense of expectancy among a crowd intent on the same object; the concentration of the one active sense, sight, on a very bright clearly defined patch of flickering light—all favour an actual hypnotic condition, particularly in the introspective type of child The emotional content of the film message may thus become sunk in the subconscious mind, to affect the reactions of the child in the many ways that such buried material is known to do As an illustration he notes the case of a girl, already sensitive, introspective and backward, who saw a film of high "artistic" merit depicting scenes of war and desolation; from the moment of seeing the film she presented a fundamental alteration of character involving periods of extreme mental confusion amounting almost to stupor She is now under treatment, and it may be noted that modern methods of treating a patient of this kind, if she is accessible to mental exploration, should establish and account for the connexion between the picture story and the mental state that ensued upon seeing it It is, in fact, the function of psychopathologists to bring such a hypothesis as Dr Newsholme's to the test of experience. The effect of the cinema has not escaped them, for it has been noted that the cinema has a possibility of stimulating so many unpleasing emotions that it serves as a touchstone to morbid anxiety The darkness, the crowd, the confinement, and the emotional stimulus of the pictures themselves rarely fail to find a weak spot in the anxiety patient, who therefore usually avoids them If an individual child is an actual or potential sufferer from morbid anxiety it does not require a hypnotic condition to produce results which the adult sufferer, wise in his generation, has learnt to avoid

It is probable that whatever harm is done by the cinema is on the unconscious rather than the conscious plane Suggestions which are recognised are satisfactorily dealt with in consciousness—one may doubt whether the portrayal of crime does more than determine the manner of its performance by a person already disposed to it But the ill-effect of 'suggestive" films, perhaps allowed in the trustful belief that the child will not understand, can arise in the very lack of understanding, for they may stir up that compound of shame, fear, and curiosity which so often exists in the childish mind At a deeper level lie unconscious tendencies that are beyond the purview of those who recognise only the world of consciousness, and if the censoring of films were entrusted to someone with psycho-analytical knowledge it is probable that a good deal would be excluded which now escapes question Themes of cruelty, for example, or of dominance or submission, would be suspect through the danger, by a blend of fear and fascination, of stirring up sleeping dogs that might never give trouble if left undisturbed The popularity of the film depends upon the ease of its emotional appeal as compared with the appeal of the written or spoken word, and it is a sound principle in child-training to allow adequate and useful expression to emotion whilst avoiding unnecessary or excessive stimulation The problem of the nervous child involves as much unhappiness and inefficiency as does that of the delinquent child, and the dangers of the cinema lie more in the nervous results of excessive stimulation than in any incentive to delinquency Dr Newsholme's essay upon the psychopathology of the films, which he feared might be regarded as remote from the matter proper to a school medical report, thus has a practical and immediate bearing upon the well-being of the child

OPHTHALMIA NEONATORUM

THOSE who study the Registrar-General's returns from week to week will have seen that hardly a week passes without 100 or more cases of ophthalmia neonatorum being brought to the notice of sanitary authorities in England and Wales, and hardly any annual report of a county health officer fails to record permanent impairment of vision in one or both eyes of some of the children thus notified During last year 186 new-born babies suffering from ophthalmia were admitted to St Margaret's Hospital from the metropolitan area, of whom 10 died, 4 became completely blind in one eye, and 20 others were left with impaired sight, and this in spite of every advantage of skilled medical attention and nursing The Scottish Board of Health two years ago, in calling attention to the serious amount of blindness still being caused by this disease, stated that in their opinion few if any cases could be treated at home with safety The Scottish health officer was advised to ascertain through his health visitors or visiting nurses the progress of these babies from day to day, in order that hospital treatment should be commenced as soon as the disease showed any tendency to become serious In London only about one-third of the cases notified reach St Margaret's Hospital, and on the average not until the ninth day of the disease when corneal ulceration may already have developed At a representative conference held in London four years ago it was agreed that one of the factors leading to delay in treatment was the dual control of midwives who are at present required to notify the case to the borough medical officer of health (when they believe that this has not been done by a medical practitioner), and also to inform their own supervising authority The circular[1] issued last week by the Ministry of Health states the decision of the Ministry to place the duty of notification solely upon the medical practitioner in charge of the case Under the new arrangement the midwife will only have two duties, on observing any inflammation of or discharge from the eyes she will, first, call in a medical practitioner and, secondly, will send word to her immediate supervisor in the midwife service—namely, the county medical officer Here her statutory responsibilities end On being summoned to see the child it is the duty of the medical practitioner to consider whether the case is or is not one of ophthalmia neonatorum If his diagnosis is negative he need not notify anyone, but the public authorities will nevertheless be aware of the case because the midwife has informed the county medical officer (in the capacity of her supervisor) that the eyes were sore and that she called in a doctor to see them On receiving this information the county medical officer, besides taking steps to find out whether the midwife ought to continue her work, will also arrange—either directly or through the local medical officer of health—that the resources of the child welfare service shall be available in case of need The officer in charge of child welfare will send a health visitor to visit the home and ascertain the conditions there, and will communicate with the medical practitioner so as to find out whether nursing or other assistance may be wanted This somewhat complicated circle thus comes back to the practitioner, up the interesting question how far group appeals are desirable Advertising in the newspapers is so expensive that the average hospital generally cannot undertake it "Such coordination of appeals," says the year-book, "as has been found by experience to be successful is on the less ambitious lines of St Marylebone Hospitals League and the Sheffield Joint Hospitals Council" It is hardly necessary to make any further recommendation of a book that has long been regarded as comprehensive and accurate, but we are glad to have an opportunity of bringing it to the notice of any reader who does not know that information about hospitals is available in this convenient form

ERRORS OF JUDGMENT IN CHEMICAL ANALYSIS

AT a recent meeting of the Society of Public Analysts Dr J F Tocher described[1] the results of an investigation into the nature of the variations of the results of determinations in chemical work, which in the main confirms the views put forward by Egon S. Pearson[2] concerning the existence of a secular movement for each observer when observations are made day after day, and also a sessional movement within a single series of observations made in one day The experiments were carried out in three series as follows (1) weighings of a sovereign by students to illustrate the want of sufficient experience, skill, and adequate training, (2) weighings of a piece of lead by skilled workers, and (3) determinations of the concentration of approximately 0 5 N sodium hydroxide solution to illustrate variations in volumetric work by a skilled worker An important psychological factor was brought out by a calculation of the mean values for succession of observations for a forenoon, the so-called sessional movement thus revealed was shown to be irregular but periodic in character—a result which is at variance with the usual assumption that, for an observer in normal health, variations in personal judgment are due to accidental errors and may be taken as randomly distributed in accordance with the law of frequency described by the normal or error curve The foregoing observations are of quite a preliminary character, and more numerous and properly conditioned experiments are required to show definitely the nature of the variations in personal judgment in chemical work Variations in the quality and quantity of indicator used and environmental factors would have to be taken into consideration, and several directions for future work are outlined in the paper Some of Dr Tocher's deductions did not pass without criticism in the discussion which followed his paper

THE SALMONELLA GROUP.

IN a report[3] just issued by the Medical Research Council Mr Bruce White B Sc, tells the story of his investigations upon the Salmonella group of micro-organisms from the stage at which it was left in Report No 91, published in 1925, in association with Dr W G Savage The two together represent the most extensive study yet published of the serological and other differences exhibited by the different members of this group The subject is one of great complexity which becomes more complicated with the discovery of fresh types and of the fact that many of these types can and do exist in different phases Further confusion arises from the varied nomenclature used by different workers in this and other countries and from the fact that the various experimental methods employed are not always comparable Mr. White's patient and laborious studies have thrown much light upon the relationships of these different types

The first section deals with the interrelationship of the Suipestifer-Hirschfeld type a large number of strains from various sources being serologically compared Relying mainly upon serological characteristics, but also allowing weight to cultural and biological characteristics, Mr White recognises four subtypes, which at present and tentatively he finds can be grouped according to their geographical predominance as (1) American, (2) Eastern (the Hirschfeld type), (3) Western European, (4) Glässer-Voldagsen subtype which is also European The subtype (1) so far has only been found in swine in America, the Hirschfeld type only as a cause of human diseases in the East, subtype (3) has been found in paratyphoid fever and food poisoning in man, but also occurs in infections in the pig and monkey The Glässer-Voldagsen strains have only been found as a cause of disease in swine on the European continent The whole group probably represents a type which is undergoing divergent evolution along several lines, modifications arising rather by suppression of certain characters—e g, dulcite fermentation—than by divergence by the development of new properties Dealing with some of the other Salmonella types it may be noted that a new type, "Type L," is described, obtained from a food poisoning outbreak at Reading, while the type mentioned as Breslau, and much referred to in German literature, is definitely identified with the Aertrycke type of English bacteriologists

A large section of the report is taken up with a study of serological variation in the Salmonella group The subject is complicated by the fact that three important and distinct forms of serological variation are found to occur within the group One of these is the "rough" variation from the smooth parent organism, a modification to which the author attaches great importance A second variation is that of the "H" and "O" forms which are related to heat-labile and heat-stable receptors The third is the occurrence of two phases, the specific phase and the non-specific phase, as originally described by Sir Frederick Andrewes Very numerous experiments are described which throw much light upon these variations and the relationship between them The "H" and "O" forms are of considerable practical importance since each group of receptors labile and stable respectively stimulates in the animal body its own special agglutinins to which and to which alone, it reacts in its own characteristic way The types of agglutination deposits are different—i e, floccular and granular In a very clear and interesting account of the literature of this type of variation the author brings the studies upon flagellar and body agglutinins into line, and gives grounds for believing that these agglutinins are coincident with the "H" labile and "O" stable antigens as originally described by Weil and Felix

Sections III and IV deal with further observations on the antigenic structure and relationships of the Salmonella types They contain a very large number of observations based upon an immense mass of experimental research Most of them deal with the serological relationship of the known types The puzzling relationship of *B typhosus* serologically to the Stanley type of Salmonella was studied, and Mr White reaches the conclusion that it does not seem possible to exclude *B typhosus* from the Salmonella series *B morbificans bovis* is recognised as a special type The fowl typhoid types (*B sanguinarium* and *B pullorum*) have hitherto been regarded as outside the true Salmonellas, but the author concludes that these are degenerate strains but of true Salmonella ancestry and must be included

Section V deals with the phylogeny and classification of the Salmonella group Mr White approaches them from an evolutionary standpoint and relies mainly upon serological characteristics, giving but little weight to cultural and biological behaviour. While much of this discussion is theoretical it is justified by the massive array of experimental work and at least gives some coherent view of the relationship of the different members of the group As an example of his methods it may be mentioned that since, for the types which exhibit "specific" and immediate result is a decompensation which is followed immediately by congestion of the kidney and important interference with the secretion of urine This is shown, as Prof Cabot remarks, by the sharp drop in renal efficiency almost always noticeable in the first few days after drainage has been started—a drop which sometimes suggests that the kidney's condition has been made worse rather than better by relieving the obstruction Following decompensation there is infection to be reckoned with, this is the second of the operative risks "There is, I think, no method," says Prof Cabot, "by which infection of a urinary tract hitherto uninfected, which has been subject to obstruction and back-pressure, can be avoided . and in the case of the infected patient you must probably face an increase of infection" To drain the bladder and remove the prostate at one sitting, thus lays a patient open to the effects of decompensation and infection immediately after the insult of operation, and to this practice is attributable, he considers, the mortality of 25–30 per cent which good surgeons recorded a quarter of a century ago Nowadays it is recognised that where a patient's condition is shaky, the three blows should be inflicted at such intervals that he can withstand them separately; this is done, of course, by draining the bladder some weeks or months before going on to remove the prostate Such drainage can be effected by a preliminary cystotomy or by means of a catheter In a paper[3] based on over 500 cases Prof G de Ilyes, of Budapest, recently declared his general preference for the tied-in catheter on the ground that openings into the bladder maintained over a long period give rise to perivesical adhesions which are troublesome when the prostate is being removed later Prof Cabot, on the other hand, condemns the catheter, because it is apt to give only obstructed drainage, which is probably worse than no drainage at all In about half the cases, he says, the tied-in catheter is unsatisfactory, either it is gravely uncomfortable or it does not drain This failure may be due to the peculiar conformation of the neck of the bladder, which makes the vesical end of the catheter stick straight into the air, or it may be due to intermittent plugging of the opening into the catheter by pus or muco-pus from bladder or kidney In a proportion of cases the bladder, ureters, and renal pelvis form a continuous canal, and obstructed drainage means a constant backwash and transference of vesical infection to the kidney in a way which destroys the results of drainage, there is always the chance, moreover, that pressure of the catheter against the middle lobe of the prostate will cause ulceration—an uncomfortable and even disastrous complication From this Prof Cabot concludes that suprapubic drainage is desirable; it is easily performed, if necessary under local anæsthesia, and causes little upset to the patient Renal decompensation follows, and afterwards infection, but not immediately This infection he regards as not wholly objectionable, so long as it is separated from the actual operation of prostatectomy Removal of the prostate without preliminary drainage inevitably leads to infection of the upper urinary tract, but if infection has previously been incurred the patient has probably got a temporary immunity which will ward off the dangers following prostatectomy itself

[3] Special Report No 103, H M Stationery Office 1926 5s

These, then, are the main advantages of preliminary drainage, and they certainly suggest its employment in all cases where the result of a one-stage operation is at all in doubt To decide definitely whether such drainage is necessary, and on the time it must continue, it has first to be ascertained what is the renal efficiency and also what is the general health of the patient Various tests of renal function are available; their merits are still in dispute, but what is important is that a surgeon or pathologist should get to know the significance of those he employs Dr J Marrack and Dr S Robinson, of the London Hospital, give an interesting account in our present issue (p 369) of comparative results of estimating blood-urea, urea concentration, and excretion of phenolsulphonephthalein; their results indicate especially the value of finding out the blood-urea content, the urea-concentration test being useful as a supplement On the other hand, as has also been shown by I Cohen, E C Dodds, and Shorney Webb,[4] a low urea content in the blood cannot always be regarded as an indication that renal function is normal, and these investigators came to the conclusion that the non-protein nitrogen content and uric-acid content of the blood were the most reliable guide to prognosis Their figures indicated that the upper limit of safety for a one-stage prostatectomy was 50 mg. per 100 c cm for non-protein nitrogen and 3 5 mg per 100 c cm for uric acid Where the amounts were higher they recommended preliminary cystotomy Such drainage, if the patient survives, generally improves the renal efficiency, and the question then arises How long should it be continued? Prof. Cabot answers this by saying that drainage should continue until the patient's renal function is as good as it will become That is universally less than what is regarded as normal function, partly because a great many of the patients are about 70 years of age. When the efficiency has become stable it may be assumed that the optimum has been reached; function will sometimes improve, slowly at first, until the kidney is working fairly well—better perhaps than it can continue to work, but as long as the efficiency is still variable it is unwise to finish the operation In the average patient, who has not had prolonged retention, who has little residual urine, and whose urinary tract is already infected, two or three weeks' drainage will probably be enough The patient with uninfected urine should have six or eight weeks to get over decompensation and to acquire a moderate chronic catarrhal pyelitis But in those cases in which renal function has been seriously impaired it may be necessary to continue suprapubic drainage for months, or even years, until the patient has got over his period of low renal function so far as he can

HOSPITALS AND CHARITIES

A PREFACE to the 1926 edition of "Burdett's Hospitals and Charities"[5] states that changing conditions have made it possible to reduce some of the sections and have allowed the inclusion of more interesting facts This year-book, which was founded by the late Sir Henry Burdett and is now in its thirty-sixth year, contains nearly 1000 pages of information about hospitals and allied charities throughout the British Empire The early chapters are devoted to the great funds and organisations, and there is an interesting discussion on hospital advertising by way of introduction Especial reference is made to the St Marylebone Hospital League and to the Sheffield Joint Hospitals Council, of which it is remarked "Both enterprises are much more than agencies for raising money, and are successfully organising hospital work no less than income in their respective areas While making hospital contributions as nearly universal as possible, they are coordinators also, and, looking beyond finance, they help and educate their members in the benefits as well as in the duties of civic responsibility" From the successes and failures of the appeal for funds made last year by the Westminster Hospital the moral is drawn that an appeal campaign should be concentrated and intensive, and that advertising is almost useless without the support of every other kind of stimulant, in letters, on posters, on the screens of cinemas and theatres, and, if possible with some sporting or cumulative effort Mutual cooperation between hospitals issuing appeals is absolutely necessary, they must warn each other of their plans, and this brings

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CLXXXVI

THE TREATMENT OF ACUTE IRITIS.

It may appear a truism to state that the first and most important step in treatment is accurate diagnosis, but nevertheless in dealing with the question of acute iritis this point must be particularly stressed, since in this case a mistaken diagnosis may lead to one of the gravest possible errors of treatment Patients with either acute iritis or acute glaucoma complain in the first instance of redness and pain in the eye accompanied by disturbance of vision It is of paramount importance to distinguish between the two diseases since their treatment is diametrically opposed and in either case injudicious treatment may be fraught with the most serious consequences

Differential Diagnosis

Acute iritis may be distinguished from acute glaucoma by means of (1) the condition of the pupil, (2) the depth of the anterior chamber, (3) the intraocular tension, and (4) the subjective symptoms

1. *The condition of the pupil* is of the utmost importance. In iritis the pupil of the affected eye is smaller than that of its fellow It reacts sluggishly (and often irregularly) to light In glaucoma the pupil is semi-dilated, usually vertically oval in shape, and absolutely immobile

2 *The anterior chamber* is deep in iritis and very shallow in glaucoma

3 *The intraocular tension* is variable in iritis It is usually slightly raised and becomes higher the greater the involvement of the ciliary body—i e, in iridocyclitis In glaucoma the eye is stony hard The estimation of the intraocular tension, especially in painful eyes, requires a certain amount of practice and experience, but the extreme hardness of the glaucomatous eye can usually be appreciated with ease.

4 *Subjective symptoms*—In acute iritis the pain is referred to the eye and to the region of distribution of the ophthalmic division of the fifth nerve only In glaucoma it is much more severe, often spreads to the areas supplied by the second and third divisions of the fifth and may be accompanied by vomiting and collapse Disturbance of vision in iritis depends directly upon the degree of turbidity of the aqueous and is seldom reduced below 6/18, while in glaucoma it is seriously impaired, appreciation of hand movements or even perception of light only being present.

Other signs of iritis, such as posterior synechiæ (adhesions of the iris to the anterior capsule of the lens), greenish discoloration of the iris, turbidity of the aqueous, &c, may be immediately obvious and will clinch the diagnosis, but they may be hard to discover without elaborate methods of examination In some cases of acute iridocyclitis with raised tension and œdema of the cornea, the diagnosis may be one of extreme difficulty, and the recent improved method of focal illumination by means of the slit-lamp[1] and binocular microscope may be employed with advantage, since it will show definitely the presence or absence of even a slight amount of aqueous haze or a few minute deposits on the back of the cornea

The question of diagnosis being settled in favour of iritis, the treatment must be carried out thoroughly if serious complications are to be avoided In all cases an attempt should be made to ascertain the cause, since treatment to be efficient must be general as well as local[2]

Local Treatment

The objects of local treatment in iritis are three· 1 To dilate the pupil so that the risk of adhesions forming between the iris and the anterior capsule of the lens is reduced to a minimum 2 To place the iris and ciliary body at rest 3 To relieve the congestion and pain

Mydriatics

A mydriatic should be instilled into the affected eye as soon as possible A 1 per cent solution of atropine sulphate is most commonly used, but in severe cases an ointment containing 1 per cent or 2 per cent of the pure alkaloid may prove more efficient, as it is easier to apply, and its action is more continuous The atropine must be pushed until full dilatation of the pupil is obtained, after which it is only necessary to maintain this condition. In obstinate cases it is better to increase the frequency of the application (every two to three hours will usually be sufficient) rather than the strength of the preparation, though occasionally it may be necessary to make a single application of a small particle of solid atropine This should always be done by the surgeon himself, who must see that the patient keeps the lachrymal passages occluded with the finger during its action, otherwise severe symptoms of poisoning may result There is little risk of poisoning with the 1 per cent. ointment, though a fair number of patients will complain of dryness of the throat after it Watch must also be kept for signs of "atropine irritation" which may come on in susceptible individuals after a day or two, usually not immediately It is characterised by extreme congestion of the conjunctiva with œdema and redness of the skin of the lids, often spreading to the cheek and resembling erysipelas If it occurs some other mydriatic (hyoscine, scopolamine, or duboisin) must be substituted and the affected skin treated with a cooling preparation such as zinc ointment or calamine lotion

The Application of Heat

The use of a mydriatic alone often does wonders in decreasing pain and congestion, but it is usually wiser to combine it with the application of some form of heat The simplest form of hot application is the fomentation, but this needs to be very frequently changed and is apt to produce a sodden condition of the lids. It is, therefore, better that the patient should bathe the eye thoroughly with boracic lotion as hot as can be borne for a quarter of an hour at a time every three to four hours covering it in the intervals with a heated pad of dry sterilised wool. This hot bathing can be most efficiently carried out by means of an ordinary wooden spoon, the bowl of which is covered with lint The patient dips this in a basin of hot lotion and applies it to the closed lids, repeating the process and adding more boiling water as the lotion cools If preferred, dry heat alone may be employed. For this purpose a Japanese muff warmer will be found invaluable It can be lightly bandaged over a pad of wool placed on the closed lids and will keep hot for a considerable period

Leeches

In cases where there is much hyperæmia and severe pain a couple of leeches may be applied to the temple just behind the external angular process The bleeding may with advantage be encouraged by warm sponging after the leeches have dropped off Relief is considerable and almost immediate.

General Treatment

Every effort must be made to ascertain the cause Syphilis, gonorrhœa, rheumatism, gout, diabetes, and tubercle must be considered Occasionally the appearance of the eye may give a clue to the cause In syphilitic cases there is a good deal of exudate and a tendency to the formation of broad synechiæ Iritis of this type is most common in the secondary stage, and a search should be made for accompanying skin lesions and faucial ulceration. In the tertiary stage a gummatous iritis may occur with localised nodules on the iris In the rheumatic and gonorrhœal types (which may be difficult to differentiate) the exudate is less dense and has a greyish gelatinous appearance A tuberculous iritis alone is rare, it is usually accompanied by a cyclitis Pain is not a marked feature but dimness of vision may be severe owing to the presence of cellular deposits on the back of the cornea (K. P.).

---

[1] T Harrison Butler Clinical Use of the Slit Lamp THE LANCET August 14th 1926

[2] Traumatic iritis due to direct infection through a perforating wound is not here dealt with, nor is the iritis of sympathetic ophthalmia.

"non-specific" phases, all are inter-agglutinable freely in the non-specific phase, this can only be attributed to the existence of a common factor or group of factors running through the entire series of types named, but unknown elsewhere In the distribution of the other non-specific factors there is much irregularity, but everywhere overlapping occurs which welds this series of types together into an intricate but compact system From these facts he accepts the series of diphasic types as derived from a single ancestral source The monophasic types offer greater difficulties but show definite general evidence of relationship Both monophasic and diphasic types show sound agglutinative evidence of true relationship to one another, and the grouping, originally on cultural grounds, is sound It is of interest to note that the *B enteritidis* type is considered as the most primitive of known Salmonellas and that the others branched off from this strain

As Mr White points out, a deeper study of antigenic relationships, far from suggesting a rational method of subdividing the group, has proved more than ever destructive to such an idea Several forms hitherto excluded have had to be included and the varieties in the group are more complicated than ever His final, but still tentative classification, is as follows —

Meta-Salmonella Types—Pullorum and Sanguinarium.

Monophasic Series—(1) Paratyphosus A, (2) Typhosus, (3) Enteritidis, (4) Derby, (5) Abortus Equi, (6) Dar-es-Salaam

Diphasic Series—(1) Paratyphosus B, (2) Stanley, (3) Aertrycke, (4) Newport, (5) Morbificans Bovis, (6) Reading, (7) Sendai, (8) Suipestifer-Hirschfeld

Some may feel that theoretical conceptions of this kind as a basis for classification are out of place or at least premature It is, however, quite certain that the present welter of unconnected facts and observations about members of a large group of bacteria is not likely to be diminished until some coherent scheme of relationship is established between their different members, and to evolve such a scheme an evolutionary basis is probably the most helpful

A MODERN PILGRIMAGE

THE Order of the Hospital of St John of Jerusalem, though fallen in some measure from its former high estate, yet continues in the body of the Grand Priory of England to carry out the precept of the first Master of the Order, the blessed Raymond du Puy, to the effect "that the Knights who should make their profession in it should adorn their Knighthood with a true Charity, the mother and solid foundation of all Virtues" Apart from its great work in organising first-aid and ambulance, the Order maintains an ophthalmic hospital at Jerusalem After the Great War the members of the English Priory were anxious to visit the ancient homes of the Order in Jerusalem, Rhodes, and Malta, and the various scenes of the doings of the Order in the East, an official pilgrimage was therefore arranged leaving Venice by sea on March 4th last and going by way of Jerusalem and Haifa to Cyprus, Rhodes, Malta and so back to Venice They had an extraordinarily interesting journey and Colonel King gives an excellent account of it in an official journal now published [1] It should be of interest to compare the accounts of their comfortable journeys with that given by an earlier pilgrim to the Holy Land The unhappy Father Felik Fabri described his sufferings on the galley about the year 1480 in the vivid phrase· "Multis noctibus fui, quod nunquam clausi oculum" The most striking episode of the recent pilgrimage was the corporate communion of the pilgrims in the ancient conventual church of the Order in the Muristan It dates from the sixth century and is now known as Mar Hanna, which should be a Syriac title Colonel King gives an admirable photograph of the interior of the building Everywhere the pilgrims met with courtesy and unbounded hospitality, and the journey must have left unforgettable memories

TUBERCLE-FREE MILK.

To ensure that a herd of cows shall supply milk free from tubercle bacilli it is necessary to eliminate all those animals which react when tested with tuberculin. Unfortunately, this is a troublesome and expensive thing to do The extra cost of the tuberculin-tested cow varies, of course, in different places and under different conditions, but the estimate of £2 5s per annum, given a few months ago at Reading,[1] is probably not too high. The average loss on every cow that reacts positively and has to be got rid of may be taken as somewhere about £10, and strict precautions must be taken against infection, so that unless there is a large demand for Certified or Tuberculin-tested milk the farmer may find his adventure into hygiene somewhat unremunerative It has its compensation, however, in a lessened morbidity amongst the animals, and the number of tubercle-free herds in this country is steadily increasing We learn with regret from Sir John Robertson's annual report on the health of Birmingham that during 1925 the number of such herds included in the Birmingham tubercle-free scheme fell from 24 to 22 Even where a good market is assured the farmer's difficulties do not end with the removal of reactors from his herd, for he is faced with the necessity of keeping up the number of his stock, which can only be done by breeding within the herd or by importing fresh blood Opinion differs as to the qualifications required of an animal before its introduction into a tubercle-free herd Some authorities consider that it should be kept apart until it has been tested, quarantined for six months, and again tested with negative result, this is perhaps a counsel of perfection and is certainly a costly proceeding Prof. G H Wooldridge, at the Reading conference, advised a medium course and said that no animal should be admitted straight into the herd unless it comes from another tubercle-free herd, and that in general one month's isolation is needed in case the cow, although not at present reacting to tuberculin, should be suffering from infection as yet undeveloped Most of the troubles of owners, he remarked, were caused by cows being given the benefit of the doubt Under the Birmingham scheme 15 of the herds are maintained by breeding, but even here constant vigilance is necessary, and last year seven of them had reactors at the half-yearly tests It must be remembered that cattle long kept away from all tuberculous infection are likely to lose their immunity and may become so susceptible as to succumb at the first opportunity This problem seems to present epidemiological problems for further study At the present time tubercle-free herds are comparatively rare, and nearly all milk is derived from herds which have not been tested, but more and more care is being taken to discover and remove cows which are supplying frankly tuberculous milk In Birmingham, of 681 samples examined 52 were found to be infected with tubercle bacilli, and in most cases the offending animals were followed up and slaughtered The Tuberculosis Order, which came into force on Sept 1st, 1925, has been helpful in securing the elimination of these cows because it provides some means of compensating their owners The technique employed for the discovery of infection seems to be variable, for the results of sampling in different areas are remarkably different In the annual report of the medical officer of health for Glasgow for instance, it is stated that 360 samples of mixed milk from road and rail transport and from milk supplied to the hospitals were examined for tubercle bacilli without any being found, which suggests an improbable superiority over milk in the Birmingham district transport of dead bodies to the Holy Places in Mesopotamia, and of the Hejaz Railway The disappearance of an efficient international organisation, aimed at checking the spread of disease by those various channels, and its replacement by a purely Turkish body, must naturally raise the question whether the health of Europe may not be seriously menaced by the change The menace is, perhaps, considerably less serious than it would at first sight seem to be, for, *with the vast territorial changes* brought about by the war, the task of the present Turkish sanitary administration has been immensely reduced and simplified, both as regards the area for the sanitary supervision of which it has assumed responsibility and the problems which it will have to solve The two Moslem pilgrimages, Sunni and Shiah, no longer take place on Turkish territory, the Hejaz Railway has passed to other Powers; the majority of the large lazarets (such as those of Basra, Khanikin, Camaran, Jeddah, Clazomene) and health offices that the Board administered are now administered by the sanitary authorities of various other countries Briefly, indeed, the principal—almost the sole—really important charge laid on the *present Turkish Administration is that of applying* measures in the Straits (Bosphorus, Sea of Marmora and Dardanelles), and we have little doubt that this question will continue to engage the attention of the permanent international health bodies of Geneva and Paris

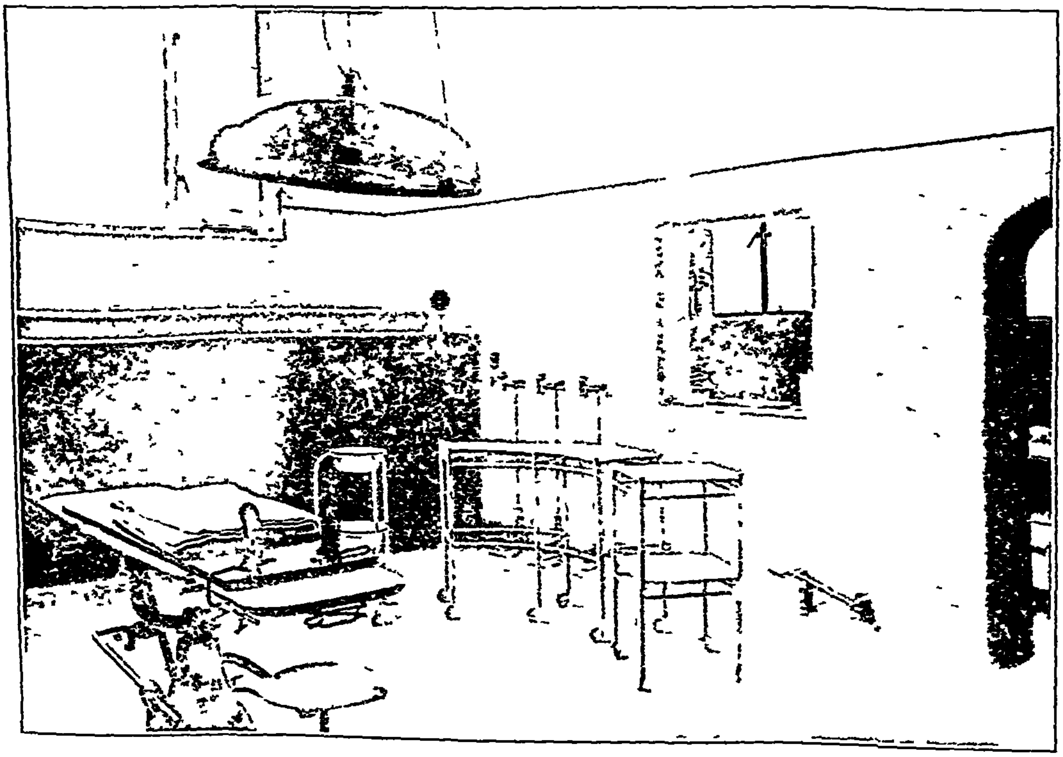
A MODERN OBSTETRIC THEATRE

PART of a theatre on the fourth floor of the new Obstetric Hospital presented to University College Hospital by the Rockefeller Foundation and opened last June is shown in the accompanying photograph

On the extreme right is seen a doorway into the theatre sterilising room, where there are sterilisers for bowls, instruments, hot and cold water, and saline solution The outlet pipes for water and saline run through the wall into the theatre where the supply is regulated by pedals, the taps and regulators are seen to the left of the hatch or window in the dividing wall The two instrument sterilisers are placed at the level of this hatch, and by means of the pedal just below it the covers of the sterilisers can be raised and the instruments taken through the hatch by those in the theatre, which makes it unnecessary for anyone to pass in and out of the theatre during operations Ventilation is so arranged that the steam from the sterilising room is drawn out through the roof and does not escape into the theatre The main dressing steriliser is in a separate room and all the sterilisers are heated with steam from the main boilers Near the theatre is a washing-up room for the surgeon and assistants, whilst anæsthetic and recovery rooms open out of the theatre itself There are two galleries for the use of students, who gain access to them from the floor above and not through the theatre itself One of them is on the theatre floor level immediately below the north window and is seen to the left of the photograph. The other is higher up and has a plate-glass screen cutting it off from the main theatre At the end of the gallery will be seen one of two movable projection lamps on a ball-and-socket joint for illuminating the field of operation in the lithotomy position For general purposes the theatre is lit by flush ceiling lights, whilst for operations the Scyalitica shadowless lamp hung from the centre of the ceiling is used The floor is made of marble terrazzo paving, and the walls, up to the height of 8 feet, have a light green Biancola marble finish; above this enamel paint is used The junction between walls and floor is rounded



NEW OBSTETRIC THEATRE AT UNIVERSITY COLLEGE HOSPITAL.

The age of the patient may be of some assistance An iritis occurring in infants is almost certainly syphilitic in origin Tubercle is more common in adolescents, while acquired syphilis and gonorrhœa usually make their appearance between 20 and 40, and gouty and diabetic cases often occur in later life In all doubtful cases a search should be made for septic foci—e g , teeth, nasal sinuses, tonsils, &c

In all cases treatment should commence with a sharp purge, and attention to the bowels should be continued throughout the attack The patient should be confined to the house, and if possible to bed Aspirin should be given for the relief of pain It is seldom necessary to resort to morphia In syphilitic cases it is essential to get the patient under the influence of mercury as soon as possible and a full course of antisyphilitic treatment should be instituted In both the rheumatic and gonorrhœal cases sodium salicylate is of benefit and should be given heroically. It is best to start with a 10 gr dose every four hours and increase this rapidly by decreasing the interval between the doses until definite signs of intolerance (headache, buzzing in the ears, and deafness) are produced The use of vaccines during the acute stage is not to be recommended

In the tuberculous cases attention should be paid to the environment Open-air treatment, adequate rest, fattening foods, and attention to septic foci are all essential Tuberculin injections appear to do good in a certain number of cases, and more recently excellent results have been obtained by generalised ultra-violet irradiation It must, however, be realised that the tuberculous cases tend to pass into a condition of chronic iridocyclitis, one of the most difficult of eye diseases to treat

Operative Treatment

No operation is ever necessary in the acute stage of a pure iritis In cases of acute iridocyclitis with raised tension a paracentesis may occasionally be performed, but conservative measures are usually successful Operation is only required for complications of iritis due in most part to inefficient treatment during the acute stage Posterior synechiæ, exclusio and seclusio pupillæ, iris bombé, secondary glaucoma, and cataract may all call for operative interference later, but it is out of place to deal with them here, since it is the object of early treatment to avoid their occurrence

Prognosis

The patient should be reassured as much as possible, but every effort should be made to impress on him the necessity of thorough treatment, which must be kept up even after the subsidence of acute symptoms A mydriatic should be used for at least a fortnight after all pain and injection have disappeared or there is a danger of recurrence The syphilitic cases should be warned to carry out treatment in detail, since, although a recurrence of iritis is improbable, it is usually a sign of a severe infection In rheumatic and gonococcal cases the prognosis with regard to recurrence should be more guarded as it is difficult to eradicate the cause In tuberculous cases the outlook is always grave, both for the eye and because there is a possibility of general dissemination

IDA C MANN, M B , F R C S Eng ,
Assistant Surgeon to the Central London Ophthalmic Hospital, Ophthalmic Surgeon to the Elizabeth Garrett Anderson Hospital

---

EXTENSION OF ST BARTHOLOMEW'S HOSPITAL, ROCHESTER —The buildings of this ancient institution, which was founded in 1078, reconstituted in 1858, and reopened in 1863, are in certain respects inadequate, and a fund of £80,000 is being raised for necessary extensions It is proposed to increase the number of beds from 105 to 157, to enlarge the orthopædic and out-patients' departments, to provide a self-contained theatre for minor operations in an improved casualty department, and new X ray rooms, and to make other additions and improvements, including further accommodation for the nursing and domestic staffs

Special Articles.

THE INTERNATIONAL SANITARY BOARD OF CONSTANTINOPLE

IN the autumn of 1914, a few weeks before Turkey came into the war on the side of the Central Powers, the Constantinople Superior Council of Health ceased to exist as an international body By a stroke of the pen the Turkish Government eliminated the foreign delegates and converted the Council into a purely Turkish organisation Under the Treaty of Lausanne of 1923 the demise of the Board was formally recognised, but it was at the same time stipulated that a special Commission should be set up to liquidate its affairs and administer its estate The nature of the Commission's mandate is clearly laid down in Art 116 of the Treaty —

> "Turkey undertakes to respect to the full the right of dismissed sanitary employees to an indemnity, to be paid out of the funds of the former Superior Council of Health of Constantinople, as well as all other established rights of the employees and ex-employees of that Council and their heirs All questions relating to these rights, to the destination to be given to the reserve fund of the former Council, to the final liquidation of the former Sanitary Administration, and all other similar or connected questions, will be decided by a Commission ad hoc, which will be composed of one representative of each of the Powers formerly represented on the Superior Council of Health of Constantinople, with the exception of Germany, Austria and Hungary In case of disagreement among the members of that Commission on any question relating either to the above liquidation or to the affectation of the funds remaining after that liquidation, any Power represented on the Commission will have the right to refer the matter to the Council of the League of Nations, which will give the final decision"

This Liquidation Commission held its first meeting on Feb 19th, 1925, and its final meeting on June 12th of this year The task with which it was charged was by no means a light one On the one hand were a large number of ex-employees of the former Turkish Sanitary Administration, whose career and prospects had been blighted by the changes brought about in the Board, and an even larger number of pensioners whose established rights had been seriously threatened by those changes, on the other was an entirely new and purely Turkish Sanitary Administration, which claimed to be regarded as the lineal successor of the former Administration and, as such, to be entitled to at least a portion of the latter's estate Fortunately the reserve funds of which that estate was mainly composed were not only considerable in amount, but, being placed in various Government stocks of the first character and deposited mainly in English and French banks, had survived the war almost intact and were at the disposal of the Commission to meet the above conflicting claims

With the completion of the work of the Liquidation Commission a not unimportant chapter in the history of international disease control comes to its final close For over three-quarters of a century the Constantinople Board of Health had shared with the corresponding body in Alexandria the task of endeavouring to keep plague, cholera, and other pestilential diseases from penetrating into Europe from their endemic centres in the East Of the nature of the barriers which it set up against those diseases a clear idea may be gathered from articles that have appeared at intervals in THE LANCET.

The task of the deceased Board was, indeed, a complex one It administered many large lazarets and health offices extending from the Persian Gulf and Turco-Persian frontier on the East to the coasts of Albania on the West, and from the shores of the Black Sea on the North to those of Arabia and the Cyrenaic Peninsula on the South It was charged by successive international conferences and conventions with the sanitary control of the Moslem Haj to Mecca and Medina, of the Shiah pilgrimage and not apply in respect of prescriptions given by Frederick George Lewtas, M.R.C.S., L.R.C.P., at present residing in the Slade Nursing Home, Bideford, Devon. A prescription signed by Dr. Lewtas will therefore not be any authority for the supply of any of the drugs to which Part III. of the Dangerous Drugs Act, 1920, applies, and any person supplying the drugs on such a prescription will be committing an offence against the Acts. Dr. Lewtas's authorisations as a duly qualified medical practitioner to be in possession of and supply raw opium and the drugs to which Part III. of the Act of 1920 applies were withdrawn in June, 1925.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Vienna Dermatologists.

Prof. Ernst Finger, director of the first dermatological clinic of the University, has reached his seventieth year and, according to the regulations, should now retire. But in view of his exceptional knowledge and experience the Senate has asked him to continue for an honorary year at the clinic so that his services may be still at its disposal. Prof. Finger is one of those rare men who combine the qualities proper to the physician, the teacher, the investigator, the organiser, and the critic. His comprehensive personality has won the admiration and affection of countless students and patients and has given him high international reputation. Since his work began in 1880 it has covered most of the field of venereology. Besides his investigation of the gonococcus and his experiments (with Landsteiner) on syphilis in apes Prof. Finger has been responsible for various dermatological studies, especially on tuberculous and atrophic conditions of the skin and on the problems of immunity. More recently his attention has been turned to social medicine, and to his unceasing efforts are ascribed the immense benefits of energetic treatment of venereal disease in the Austrian army during the war. He organised a hospital for prostitutes, which was the first of its kind on the continent, and his text-books have been translated into most European languages.

Prof. Leopold Arzt succeeds Prof. Gustav Riehl as chief of the second dermatological clinic. He was born in Vienna and has spent his whole life in the city, which was undoubtedly one of the reasons for his being preferred to others nominated for the appointment: there is nowadays a tendency to refrain from calling in men from abroad to the leading positions. His scientific attainments, moreover, are certainly sufficient.

The Weight of the Brain.

Dr. Pape and Dr. Kopelzky have reported on a series of 833 brains which they have examined. The average weight of the brain, they find, is 1363 g. in males and 1260 g. in females. During the first five years of life it is doubled, but during and after puberty it increases but little: the highest average weight is found in the age-period 11–15 years, when it is 1443 g. in boys and 1306 g. in girls. During the climacterium, these observers consider, the weight is rather greater than might be expected from the fact that after puberty it generally diminishes in a steady curve. The gradual diminution is due partly to atrophy and partly to the fact that many persons with heavy brains die early in life. The extremes of variation are commoner amongst men than women, perhaps because of an alleged further biological differentiation. One adult had a brain weighing 1730 g. which did not show any pathological changes, whilst a boy of 3 had a brain weighing 1700 g. Amongst suicides the average weight was found to be 100 g. more than normal and no brains classed as light occurred in this group. In all these investigations it is necessary to take into consideration the incidence of pathological conditions such as tumour and meningitis at the various ages.

Uncompleted Medical Studies.

There is a remarkable disproportion between the number of students who matriculated 6–10 years ago and the number of degrees granted by the University during the last five years. Evidently many students change their minds and take up other occupations before they reach the end of their studies, or else they complete their training somewhere else, which is unlikely since a large proportion of them come from abroad—e.g., the Balkans—and have no opportunities for study elsewhere. No doubt it is the economic factor that is responsible, but whatever the cause, only 1200 students graduated here in 1924–25, though there were 2780 first-year students in 1919–20.

(FROM OUR OWN CORRESPONDENT.)

Care of the Disabled.

OF 1,500,000 disabled soldiers in this country more than 660,000 are still in receipt of a pension. The allowance of those whose impairment of efficiency was less than 25 per cent. has been capitalised, but those disabled by more than 50 per cent. are described as Schwerbeschädigte and enjoy certain privileges—for instance, employers must find work for a certain number of them. There are 2734 blind among the victims of the war, and the pensionaries include 39,000 men suffering from tubercle whose disease was contracted or aggravated by service. Some 5000 men are registered as mentally affected, and over 44,000 have lost a leg or a foot, this disability being almost twice as common as the loss of an arm or hand. The great development of orthopædic technique, however, has enabled the majority of them to work. Since 1924 the number of applicants for disablement allowance has increased, as the bad economic state of Germany has made a pension necessary to many who were previously able to do without it. The number of widows is 365,000, and the number of fatherless children 962,000, of whom 65,000 have lost both parents. A sum of 1,491,800,000 marks—nearly £75,500,000—is spent every year on the support of war victims. This is about 30 per cent. of the whole German Budget.

Voronov's Operation.

Before the Society for Sexual Research Prof. R. Mühsam lately read a paper on the results of transplanting the testicles by Voronov's method. He gave particulars of seven patients on whom he had operated, one of whom was eunuchoid, two impotent after castration, one bisexual, and four homosexual. Shortly after operation the results seemed to be rather satisfactory, but the improvement was transitory and lasted only for periods varying from a few days to several months. The eunuchoid patient had erections for two months: the homosexual patients had dreams of heterosexual character, but were incapable of normal intercourse, and similar results were obtained in the case of those castrated. Only in the bisexual patient was the result satisfactory; his desires became male in character and at last he married and begot a child. The apparent efficacy of the operation in the early stages is obviously due to the hormonic effect of absorption from the transplanted organ.

Before the same society Prof. E. Joseph read a paper on the influence of suprapubic prostatectomy on the sexual power. He had performed the operation, he said, in 78 patients, in 52 of whom reliable answers to his question about sexual function were obtained. Only one patient said that his sexual power had totally disappeared after the operation, whilst of eight patients over 70 years of age five had regained their sexual power. Of the patients under 70 years of age, in eight the sexual power had totally disappeared before the operation and was not restored, whilst in 34 improvement was observed. As he pointed out, however, it is difficult to say whether

MEDICINE AND THE LAW.

The Legal Definition of Live Birth · A Gap in the Law.

Dr. Godfrey Carter's paper on the Legal Definition of Live Birth, read before the British Medical Association at Nottingham in July, commented upon a remarkable gap in the criminal law of England It is neither murder nor manslaughter to kill a child until it is born. So far as murder and manslaughter are concerned, the law does not deem a child to be born until the whole body of the child is brought alive into the world, having an independent circulation, and breathing, or capable of breathing, from its own lungs, so that it possesses, or is capable of, an existence independent of connexion with its mother, though the child may legally be deemed completely born in spite of the fact that the umbilical cord is not severed That is how the law is stated in Lord Halsbury's "Laws of England," and, as Dr Carter remarked, the legal requirement of evidence of an independent existence after the complete extrusion of the child seems to have arisen in the ignorant past at a time when it was believed that a fœtus drew its blood direct from its mother's circulation To this legal definition must be added two judicial decisions In 1834, Park, J., held that a child born alive could be the subject of a murder, though it had in fact not breathed; and in 1837 it was held that the fact that a child had breathed was not conclusive proof that it had been born alive, as it might have breathed and died before birth.

Dr Carter makes the points that an appreciable number of full-term healthy infants lose their lives through deliberate interference during birth, that this interference occurs in the endeavour to conceal birth, that it occurs in secret and often without the connivance of a second person, and that the law assumes the child to be born dead unless satisfactory evidence is produced to the contrary He quotes with approval a Scottish ruling given by Lord Young to a jury in the High Court of Perth in 1892, in a case of alleged infanticide, which is worth repeating

> "If the child was killed, and the prisoner was to blame for its death, she is guilty of culpable homicide If she went on from the conception to the birth of the child, desiring to hide her shame, and refrained from calling assistance when assistance was at hand and took upon herself to assist herself, and in the agony of childbirth grasped the throat of the child with the result of causing its death, I cannot say that she is not blameworthy or that her blameworthiness does not amount to culpable homicide If you think that blame does attach to her, then culpable homicide is the name for that blame, resulting as it did in the death of a child which had both cried and breathed. It does not matter in the least, so far as the criminality of the accused is concerned, if the injuries were inflicted when the child was partly in its mother's body"

But those words cannot be taken as a statement of English law, nor does English law accept without considerable reservation a dictum by the late Mr Justice R S Wright (quoted by Dr Carter as having been uttered in a case at Shrewsbury Assizes in 1901) to the effect that the test of separate existence is the question whether the child is carrying on its being without the help of the mother's circulation. The Royal Commission on Capital Punishment in 1865 recommended statutory provision for punishing the infliction of grievous bodily harm or serious injury upon a child during its birth or within seven days afterwards, and added that no proof should be required of the fact that the child was completely born. A later Commission (in connexion with the draft code) proposed to enact that "every woman shall be guilty of an indictable offence who, being with child and being about to be delivered, with intent that the child shall not live, neglects to provide reasonable assistance in her delivery if the child dies either just before, or during, or shortly after birth, unless she proves that such death was not caused either by such neglect or by any wrongful act to which she was party" This rather cumbrous clause would have met Dr. Carter's difficulty, but the recommendation has never been taken further Presumably Parliament would be unwilling to interfere with the traditional principle which leaves the burden of proof upon the shoulders of the prosecution The type of accused person at whom the change in the law would be aimed is usually the unhappy mother of an illegitimate child, an object of general sympathy. A change in the law might secure more convictions, but the whole policy of Parliament is to mitigate punishment in such cases; indeed, it was necessary to pass the Infanticide Act of 1922 because of the unreality of passing sentence upon such mothers where the death of a newly-born child was caused by some wilful act or omission at a moment when the mother's balance of mind was disturbed It is doubtful if a mother under such circumstances would pay much attention to the wording of an Act of Parliament, whether the law remains in its present state or whether it is changed as the two Commissions have recommended Dr Carter argues rightly that to place the burden of proof upon the mother would force her into the witness-box to state how it came about that the child did not survive, she would then be liable to cross-examination. But the cross-examiner would have a repugnant task, and the jury—whose undefined privilege it is to temper the keen edge of the law—would readily allow their verdict to follow their natural feelings of sympathy Nevertheless, the law is at present surprisingly unsatisfactory, and it is highly desirable that the legal definition of what constitutes live birth should be reconciled with modern science

Drunkenness while in Charge of Motor-Car Defence of Insulin Poisoning

A physician practising at Bentinck-street, W., charged at Marylebone police-court on August 13th, raised an unusual defence to a charge of being drunk while in charge of a motor-car, and driving in a manner dangerous to the public He gave evidence that his disability was due, not to alcoholic poisoning, but to an overdose of insulin, and he called four doctors who agreed in stating that the symptoms of insulin poisoning might easily be mistaken for those of alcoholic poisoning He was fined £20 with 10 guineas costs on the charge of drunkenness, and £10 on that of dangerous driving with the alternative of 21 days imprisonment The magistrate ordered the convictions to be endorsed upon his licence, and the accused was disqualified from holding a licence for 12 months. As the case is subject to appeal, further comment is withheld The evidence for the prosecution was that the defendant's motor-car about midnight mounted a pavement in St John's Wood, ran along it, recrossed the road, ran into a lamp-post, rebounded, and came to rest against a garden wall On being spoken to by a policeman, he was said to have driven across the road again into the same lamp-post The constable's evidence, confirmed by the divisional surgeon, was that the defendant was drunk.

Dentistry in the Market-place

A coloured man who was selling tooth-powder in a street in Liverpool was on August 10th fined £5 at the police-court for practising dentistry without being registered under the Act of 1878 It was alleged that he had performed an extraction with his finger and thumb so as to show his knowledge of dentistry On behalf of the defendant it was stated that no payment was made for the extraction, and the question arose whether the extraction could be described as such work as is usually performed by qualified dentists The deputy-stipendiary ruled that it could and that the defendant had obtained a reward in the way of an advertisement for his tooth-powder

Dangerous Drugs Withdrawal of Permit

The Home Secretary gives notice that he has directed that the exception in Regulation 4 of the Dangerous Drugs Regulations, 1921, which permits dangerous drugs to be supplied on a prescription given by a duly qualified medical practitioner, shall

6 The clinical history subsequent to delivery, including the amount and character of lochia; copy of temperature chart, &c

7 The time of the onset and the probable cause of pyrexia

8 Any cases of specific fevers, erysipelas, puerperal pyrexia, or other possible forms of sepsis, visited recently by doctor or other attendant, giving dates

The new Regulations come into operation on Oct 1st next The usual fee for notification will be paid

THE HEALTH OF LONDON SCHOOL-CHILDREN IN 1925

THE report of the school medical officer for the County of London indicates how negligence and ignorance the bulwarks of disease, are rapidly falling to the attacks of a wider education, witness the materially lessened mortality at the ages of comparative helplessness The enormous scope of school medical work in London can be gauged by a study of this report, prepared by Dr F N. K. Menzies in collaboration with Sir William Hamer, wherein is described an organisation designed to deal with roughly an eighth of the total school population in England and Wales There are 664,890 children on the roll, with an average attendance of 580,316 The number of routine children examined during the year was 240,365, including 41,011 leavers; 235,745 special inspections and reinspections were made The percentage of routine children requiring treatment (excluding uncleanliness and dental defects) was 42 9.

During 1925 several important developments have taken place (1) The examination of children leaving school was reinstated, giving valued assistance in vocational guidance to all care workers and employment agencies (2) Extension of facilities for treating dental defects and minor ailments (3) Inauguration of two new centres for the in-patient treatment of tonsils and adenoids (4) A new scheme for the treatment of discharging ears and the establishment of six ionisation centres (5) Further provision for remedial exercises by the formation of 100 "health classes" for treating incipient deformities, including postural curvatures, flat feet, and defective expansion of the chest—these classes are taken by skilled instructors under the supervision of the medical officer, and reports of their activity show excellent results (6) Increased provision for open-air education from 95 open-air classes in 1924 to 117 in 1925

Many parts of the country have reported a fall in the nutritional state of the children during the past year, the nutrition of the London entrants has not so far shown any falling away Dr C J. Thomas, in his detailed analysis of the work, gives his reasons for stating that there has been a real increase in the number of children suffering from enlarged tonsils and adenoids and their sequelæ, which he attributes to the effect of climatic conditions and the prevalence of infectious complaints There has been a steady increase in the percentage of children leaving school whose teeth are noted as satisfactory There has also been a definite increase of 6 to 7 per cent of the number of entrants found to have perfect teeth There is a steady decline in the number of children leaving school with defective vision—the Council's regulations now prohibit the teaching of needlework by artificial light, unless in exceptional circumstances. The all-round improvement in the general condition of the leaving child is a tribute to the care and training given during the period of school life

Dr F. C Shrubsall gives an analysis of the after-effects of encephalitis lethargica in the different age-groups, showing the higher incidence of mental changes in the child An excellent map shows that the distribution of encephalitis in London during 1921–25 followed the density of population Dr Elizabeth McVail has made a careful investigation of educational retardation in 69 girls in backward classes The proportion of these children with physical defects was much higher than amongst normal children, 16 per cent had defective vision, the same proportion had defective hearing. The effects of disabilities persisted long after these had been cured or mitigated, in particular a child who has been unable to hear gets into a habit of not troubling to listen Many children in all the groups evidently owed their school backwardness to loss of attendance due to illness or unfavourable home conditions The children in these classes are not merely behind their fellows but are so badly lacking in education that they would be severely handicapped in employment Intensive methods of education would do them little if any, good, and Dr McVail sets out the necessity for small classes under close medical supervision

That the full functioning of the mind, whatever the level of intelligence may be, is largely dependent on the well functioning of the body is increasingly brought out in many researches along different lines Dr J Nairn Dobbie, working in conjunction with the staff of the National Institute of Industrial Psychology on the subject of vocational guidance, records the physique and general condition of 237 boys and girls of 14 years, and indicates how brightness and high spirits go hand-in-hand with robust health and good nutrition. The physical contra-indications for special occupations were considered, 49 boys out of 128 showed 103 contra-indications between them, and 40 girls out of 109 showed together 80 contra-indications

Dr R H Norman has investigated the frequency of albuminuria in 1787 school-boys, and found it present in 23 1 per cent at all ages between 7 and 15 years—the incidence rising from 10 per cent at the lower age to 40 per cent at 15 years—re-examination was carried out a few weeks later and in the majority of the cases it was still present, the persistence being greatest in the elder boys

Dr Mabel Russell gives an account of the social and physical condition of children living in canal barges, and finds that the physique and general health of these children is better than that of town children, though in hygiene and education they are far below the town standards

Dr. Letitia Fairfield, in analysing 650 cases of illness among school teachers, states that prevention and treatment of functional nervous disorders are on a less satisfactory basis than is the case in purely physical disorders, and that the severity of the breakdown is in inverse ratio to the gravity of the alleged causes

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the statistics of the cities of Glasgow and Birmingham for 1925 The density of population per acre is nearly three times greater in Glasgow than in Birmingham (the ratio is 57 : 21), but the number of persons per house is less in Glasgow—namely, 4 60 as compared with 4 83

Name of city.	Estimated mid year population (R G.)	Birth rate.	Death rates per 1000 of the population					Death-rates per 1000 births	
			All causes	Tuberculosis	Cancer	Resp diseases with influenza	Heart disease	Infant mortality.	Maternal mort from childbirth
Glasgow	1,057,100	24·0	14 5	1 33	1 31	2 8	1 4	102	7 2
Birmingham	945,900	18 8	11 7	1 14	1 27	2 4	1 4	78	4 1

Glasgow.

This is Dr A S M MacGregor's first report, and during the first half of the year his predecessor, Dr A K Chalmers, was still in office He briefly describes the growth of the city. During last century it grew beyond its boundaries at a greater rate than within them After the extension of 1891 rapid building took the regeneration occurs because the general state of health is improved, or because the operation frees the seminal vesicles from the pressure of the enlarged prostate. Some of the patients complained that whilst the libido was restored no ejaculation followed, and in these cases it was ascertained that the semen was passed into the bladder. Prof. Joseph considers that suprapubic prostatectomy is likely to restore the sexual power if it has not totally disappeared before operation.

Cancer Cured by Mesothorium

Prof. Lazarus recently showed to the Berlin Medical Society a patient with cancer of the tongue cured by the administration of mesothorium. He explained that the application of the rays has three objects—to destroy the cancerous tissue, to vitalise the stroma so as to obtain fibrous encapsulation of the tumour, and to produce a protective zone by hyperæmia and cellular infiltration. The patient shown was 61 years of age and had a squamous-celled epithelioma. A 50 per cent. radiothorium was applied emitting β and γ rays. In place of the cancer, of which a photograph was shown, there was marked cicatrisation. No relapse has occurred since the treatment in 1921 and the weight of the patient has increased by 20 kg.

An Inundation Disease

An epidemic of fever from an unknown cause has been observed in Silesia, where there have been heavy floods. The disease began with high fever, pains in the limbs, and great weakness. The symptoms usually last only for a few days, though occasionally there is a second attack. The patients were conveyed to the University Clinic of Breslau, and Prof. O. Minkowski, chief physician of the clinic, Prof. K. Prausnitz, chief of the Institute of Hygiene in the University, and the district medical officer of health, who formed a committee of investigation, state that all the patients had either slept in the wet meadows or had helped to get in the hay. The disease is carried by insects, but is not transmitted from one person to another, and certainly the floods have favoured its development.

Supervision of the Preparation of Serum

In Chemnitz, Saxony, a child has died of septicæmia after an injection of the Degkwitz anti-measles serum, and examination of the serum showed that it contained streptococci. The serum was obtained from the Chemnitz municipal hospital, and it is now discovered that no bacteriological examination of it had been made. The Degkwitz serum is recommended for prophylaxis against measles, and school medical officers insist on its administration to prevent the spread of the disease in schools. Prof. A. Schlossmann, of Dusseldorf, draws attention to the dangers of preparing serum in hospitals and distributing it to practitioners without any official scrutiny, and considers that its preparation should be as carefully supervised as that of antidiphtheritic serum. Health authorities ought to ascertain who has prepared the serum and whether the necessary serological and bacteriological tests have been carried out properly.

Prosecution of a Medical Man

Not long ago a patient died of heart failure whilst undergoing fat-reducing treatment, and the medical attendant was prosecuted for having caused the death by neglect. The experts gave evidence that the condition of the heart should have been known to the doctor and that he ought to have been especially cautious and should have regularly observed the progress of the case. The neglect complained of was that the doctor left town for two days without giving orders to the nurse. The defendant pleaded that the patient, against his will had taken very hot baths in order to reduce weight rapidly, which he regarded as the principal cause of death. He was nevertheless found guilty and fined 300 marks (£15), and the family of the deceased is now in a position to bring a civic action for damages against him which is likely to cost a good deal of money.

Public Health Services.

NOTIFICATION OF PUERPERAL PYREXIA.

An Order,[1] dated July 31st, 1926, issued by the Ministry of Health, makes important new regulations regarding the notification to the sanitary authority of fever occurring in the recently delivered woman. Puerperal fever, as it is rather loosely called, has been notifiable for the last 25 years, but, owing to the fact that the condition cannot be accurately defined since the disease is not specific in the sense that scarlatina or diphtheria are specific, notification has been incomplete, with the result that the prevalence of puerperal infection is imperfectly known and measures for its prevention and effective treatment have been abortive. To some extent, too, the term "puerperal fever" has been felt to be a slur upon the patient or her medical attendant. For these reasons the Ministry has decided to follow the advice of a representative committee, which reported in February of last year, and to make it obligatory on the accoucheur to report any febrile condition occurring in a woman within 21 days after childbirth or miscarriage in which a temperature of 100.4° F. (38° C.) or more has been sustained during a period of 24 hours or has recurred during that period. This obligation is added for the present to the existing obligation to notify puerperal fever, for although it is intended to abolish the latter term altogether, this cannot be done without legislation to amend the Act of 1899. Puerperal pyrexia, as defined above, is now to be notified irrespective of the cause to which the fever may be attributed, the importance of securing adequate treatment in the early stages of puerperal infection outweighing the objection that the new rule will result in the reporting of a number of trivial cases. The Ministry has formed the impression that pyrexia during the puerperium is not infrequently looked upon as a comparatively unimportant incident, and the circular[2] impresses upon maternity institutions the fact, since illustrated so poignantly in the Kingston case, that the presence of infection, however slight in degree in a patient or in a member of the staff, should be considered as liable to give rise to an outbreak of virulent infection and should be dealt with accordingly. Local authorities are instructed to advise all practitioners within their area of the new duty imposed upon them and to supply them with forms on which to indicate whether assistance is desired in dealing with the case. In London the notification is handed on to the Metropolitan Asylums Board which has made special arrangements in its hospitals for the treatment of cases of puerperal fever. Outside London the onus is laid on the local authorities administering maternal welfare schemes to provide facilities for diagnosis and treatment, including consultation with an obstetric specialist and the provision of skilled nursing or institutional treatment. Should the practitioner desire special assistance from the local authority the medical officer of health is to ask for information from him in regard to some or all of the following points:—

1. Conditions in the patient, if any, prior to the labour, which might have been factors in producing the pyrexia—e.g., septic foci, vaginal discharge, carious teeth, &c.
2. The names of all persons who have made internal examinations, including the name of the person who delivered the patient, their occupations and professional qualifications (if any).
3. Day and hour of commencement of labour or miscarriage.
4. The clinical course of labour or miscarriage, mentioning any special means used to assist labour—e.g., obstetrical operations or manual removal of placenta, and any injuries incurred by the patient.
5. The duration of labour and time of termination of labour or miscarriage.

[2] Ministry of Health, Circular 722, issued to County Councils and Local Sanitary Authorities. 2d.

flow through an agricultural district, and the water is chlorinated before use. The third supply, from three deep wells sunk in the Bunter Beds, is only brought into use when needed. The area over these wells is becoming populated and the water from Aston well is now chlorinated Individual houses in the rural area are supplied by shallow wells In the majority of courtyard houses there is no water-supply inside the house, the service being by a standpipe in the yard The river Tame receives drainage from other towns and villages outside the city; it is grossly polluted and complaints of smell are common during the summer months A recent conference of the authorities concerned is already producing results The flooding of the Hockley Brook in 1925 caused considerable alarm and nuisance Work to prevent the flooding is in progress and expected to be complete in 1926. Efforts are being made, where practicable, to secure one water-closet for each house in the case of courtyard houses

The Gas and Electric Supply Committees are backing up the work of the public health department in striving for a purer atmosphere; there are 83,000 gas fires and 185,000 gas cookers in use. Eighty-six convictions were obtained against factory chimneys for emitting black smoke, but the average fine was only £2 2*s* 9*d* The use of coal-dust and inferior slack has led to a grit nuisance In the local Act of 1922 powers were obtained to deal with chimneys emitting grit and several firms have had to alter their plant The unaided eye cannot see the grit coming out of the chimney, but it has been found possible to trace the offending chimneys by observing the direction of the wind and putting down papers smeared with a slow-drying varnish. The use of a field-glass or telescope has also been found helpful

Birmingham does better than most towns in the building of new houses, 4840 were erected in 1925, 3066 by the corporation and 1774 by private enterprise During the last six years 13,099 houses have been put up, 8516 by the corporation and 4583 by private enterprise Three-quarters of these have been erected in the healthier suburban wards There is still much overcrowding, and in order to discover its extent information was sought at about 500 houses in each of two representative areas In the poorest area 25 per cent of the houses were found to be overcrowded, in the artisan area only 2 per cent The definition of overcrowding was "more than four persons per bedroom" or "persons of opposite sexes over the ages of 13 in the same bedroom" Some of the bedrooms are very small so that the standard adopted was obviously a low one Examples are given of some of the worst cases of overcrowding. There is a great need for decent small furnished houses, and as an experiment two-roomed houses are to be erected and let furnished to small families until the housing shortage is less, when two of these small houses may be combined into a good four roomed cottage

Dr E H R Harries is convinced, after more than five years' experience, of the value of the Schick test and immunisation for the protection of the staff of the hospitals against diphtheria Up to the end of the year the method had been extended to three large institutions for children, and it is hoped next year to give a fuller account of work on both diphtheria and scarlet fever immunisation Dr C G Dixon has had encouraging results from the artificial light treatment of various forms of tuberculosis at Yardley Road Sanatorium Dr Ethel Cassie gives an interesting account of the work of the Carnegie Infant Welfare Institute. The clinics for treatment by light and by massage and remedial exercise have done good work, and the breast feeding clinic has given striking results in the restoration of lactation. Lactic acid milk has proved valuable for cases of marasmus and chronic enteritis[1] The damage to eyesight from ophthalmia neonatorum during 1925 was unusually severe Two babies, one born in hospital and the second under the charge of doctor and midwife, were left totally blind In a third, born in a maternity hospital, both eyes were left very defective, a fourth, born in a general hospital, had slight defect of the left eye, and the fifth, also born in hospital, had the right eye slightly scarred The five cases came under treatment of the eye hospital after varying intervals—namely, three months, 23 days. 10 days, one month, and 18 days respectively

Efforts to eliminate tubercle bacilli from milk are referred to on page 398 of this issue.

TYPHUS FEVER IN GLASGOW.

As we reported last week, there has been a small outbreak of typhus fever in Glasgow By courtesy of the divisional medical officer of health we are able to give the following particulars

On the evening of July 30th a case of suspected typhus fever was admitted to Belvidere Hospital Later in the same evening the home of this patient was visited, and two younger children of the family were found to be 'febrile and out of sorts" A married daughter of the family, residing at a house some distance away, was also confined to bed with the same symptoms These three patients were immediately removed to hospital

The blood of the original patient gave a positive Weil-Felix reaction, and all contacts from both infected houses were removed to a reception house for observation. On the afternoon of July 31st one of these contacts, who had developed a temperature of 100° F, was also removed to hospital On August 1st a sister of the original case—a resident maid in a local hospital—was reported to have developed a temperature of 104°, and she also was admitted for observation to Belvidere Hospital On the following day another contact who had become febrile was removed from the reception house to hospital for observation Within a few days of admission to hospital all the contacts showed definite evidence of typhus fever. On August 10th another case of typhus fever was admitted to Belvidere Hospital This last patient was a contact with the original case

Inquiry into the history of previous illnesses in the infected households revealed that the father of the first seven cases had died on July 16th from an illness whose nature was somewhat obscure His movements were difficult to determine, and it was thus impossible to trace any source of infection The mother of the family had also suffered from an indefinite illness lasting eight days but had recovered A Weil-Felix blood reaction was in her case negative: this test was performed six weeks after the onset of the illness

The precautions adopted by the public health authorities were as follows —

1 Removal of direct contacts to a reception house for observation.

2 Daily medical inspection of these contacts, and removal to hospital of any who had developed febrile symptoms The temperature was taken morning and evening as a routine measure

3 Disinfestation, cleansing, and closure of the infected houses

4 Daily visitation of indirect contacts in various parts of the same district.

5 House-to-house visitation of all houses in the near vicinity

6 The illness of the father was regarded as typhus fever administratively, and all contacts with him in the institution where he died were treated as contacts with the disease

7 As the original case had been admitted to a general hospital in the first instance, the ward of that institution was closed for the admission of new cases, the nurses and patients of that ward were kept under observation and extensive disinfection was performed In addition the ambulance by which the patient was conveyed to the general hospital was disinfected, and both the driver and the attendant treated as typhus contacts

8 One of the later cases of typhus fever was a maid in a local institution All the direct contacts with this patient were removed to the reception house for observation The dormitory in which she slept was closed after extensive disinfection and disinfestation had been carried out

place within the enlarged area. From 1901–11 there was a decline of house building in the city and the empty houses numbered 20,000, whilst growth increased outside. From 1911 onwards the decline in house building was marked and empty houses —good, bad, and indifferent—became re-occupied. Building practically ceased in 1917 and since then it has been resumed much too slowly to meet the demand. The outside growth now taking place is of no service to the large population most in need of accommodation.

Variations which occur in ward populations are due to corporation housing schemes on the one hand and a clearance of slum areas on the other. The unoccupied houses, of which there were 18,710 in 1913, numbered 366 in 1925 and 449 in 1924. In last year's report it was estimated that 5000 houses annually for the next 20 years would be needed to meet the shortage; in 1925 only 1394 were provided. Back-lands are being gradually cleared. During last year the number of back-land tenements had been reduced to 450, and of these 50 are to be included in a clearance scheme. The houses most needed are those of moderate size, and no houses of less than three rooms are being built under subsidy schemes. In the present report is included a monograph by the late Dr. Alexander Maclean on the height and orientation of buildings in relation to sunshine, wherein it is recognised that at the latitude of Glasgow the streets have to be wider or the buildings lower than in London if they are to get the same benefit from sunshine. Proximity to place of employment is not so necessary in Glasgow, and in the interests of the children a low density with access to open spaces should be preferred to the erection of high buildings near the place of work.

The new life-tables for Glasgow show that the expectation of life for males up to the age of 42 is slightly better than in Liverpool and Manchester, but after that age it is worse. The expectation of life for females is better in Liverpool and Manchester. At birth the expectation in Glasgow is 48·41 years for males and 52·22 for females; at the age of 10 it is 50·81 for males and 53·19 for females.

Several new maternity and child welfare centres have been recently completed or are under construction; the report has illustrations of them. At four of the centres arrangements have been made for the diagnosis and treatment of venereal diseases. A special nurse has been appointed to follow up women and children whose attendances have lapsed, and her efforts have met with considerable success. Dr. Chalmers Smith reports on the light treatment in use at Cochrane-street. The cases treated have been children under 5 years of age suffering from rickets, malnutrition, and debility, and the success attained is likely to lead to a further extension of the work. At the maternity hospital a course of lectures and demonstrations has been given to midwives and will be repeated. At the instance of the Scottish Board of Health two aural surgeons have been appointed to treat the children in the isolation hospitals who contract otitis media as the result of scarlet fever or other diseases. In 1925, 3878 women attended the antenatal centres, as compared with 2957 in 1924. Midwives sent for medical help in 22 per cent. of their cases. A chart shows that the case rate for ophthalmia neonatorum per 1000 births was about 6 before the war, rose to 10 in 1917, and 10½ in 1919, since which it has rapidly declined. Since 1914 a total of 168 of the survivors have shown some degree of impaired vision, but during the last three years only 18 have suffered in this way. During 1925 there were 32 gonococcal cases, all of which recovered without impairment of vision, whilst of the 354 non-gonococcal cases two lost the sight of one eye and one had slightly impaired vision. During the last five years the average death-rate from puerperal fever per 1000 births has been 2·6. The number of cases notified last year was nearly five times greater than the number of deaths, which shows that notification is being better carried out. Of 500 consecutive cases admitted to Belvidere Hospital between April, 1923, and November, 1925, 96, or 19·2 per cent., died; in many of the fatal cases death was due to general peritonitis.

Two small outbreaks of scarlet fever were traced to the milk-supply. In each of them the infection was apparently due to missed cases which had developed otorrhœa. Since encephalitis lethargica became notifiable there have been 683 cases with 174 deaths. It is estimated that of the survivors about 200 are definitely disabled, some 25 per cent. of whom have symptoms of Parkinsonian type. Further observations have been made on the mosquitoes of the district. Six species have been identified, including only one of the anopheline type—viz., *Anopheles bifurcatus*. Deaths due to mosquito bites are attributed by Dr. W. C. Gunn to septic poisoning arising from scratching. He finds that a solution of camphor and menthol in absolute alcohol is an efficient remedy to apply to the bite. It was noted that the fogs, accompanied by a low temperature, in the latter half of November caused considerable increase in the respiratory death rate among older people but did not apparently affect children. Dr. Fergus L. Henderson reports on the use of X rays in the diagnosis of tuberculosis. He thinks that radiologists tend to diagnose hilum tuberculosis or peri-bronchial tuberculosis on insufficient evidence, but regards X rays as of considerable value and dissents from the opinion of one leading lung specialist that no radiologist should say that a chest is normal. During the last six years very few cases classed as negative have returned later as tuberculous. X rays are useful in the treatment of gland tuberculosis, but tuberculosis of the skin is better treated by ultra-violet radiation. Artificial light treatment has been in operation at Robroyston Sanatorium during the whole of 1925. One hundred and two patients of various types were treated, including ten carefully selected pulmonary cases. Dr. Alexander Smith concludes that artificial sunlight therapy is undoubtedly of great value for surgical tuberculosis, but is by no means infallible. For pulmonary disease its usefulness has yet to be proved. If used as a tonic and prophylactic for debilitated children, particularly those who have been in contact with tuberculosis, it would, he thinks, be almost invaluable.

The smoke inspector claims that 1925 will be notable for the first practical step taken by the corporation to produce a solid smokeless fuel suitable for domestic purposes. It has been named Kincole. It is said that it lights easily with paper and wood, gives out more radiant heat than the same weight of coal, and might well be substituted for coal in all domestic fires.

Birmingham

Sir John Robertson reminds us that 1925 was the jubilee year of public health effort. During 50 years the birth-rate, death-rate, and infant mortality-rate in Birmingham have been halved; small-pox and enteric fever have practically disappeared; scarlet fever has gone far towards disappearing also, and the prevalence of all the other so-called zymotic diseases has been enormously diminished. A statement gives some idea of what happens to illegitimate babies. Of 624 reported on in 1925 87 still remained in infirmaries and similar places, 51 died before the first visit was paid, and 86 removed. In 156 cases the father and mother were living together. In 48 the father was making an allowance under order, in 56 he was making a voluntary allowance, and in 106 cases he was not contributing towards upkeep at all. Investigation of the results of operation for cancer of the breast showed that early and complete operations were much more successful than the surgeons were aware of. Steps were taken to bring their success to the notice of the public by the house-to-house distribution of leaflets.

Birmingham has several sources of water-supply. The Welsh gathering ground is only used up to about a quarter of its full capacity. The rivers Bourne and Blythe are not a very desirable source; both streams same milk which would otherwise be sold as raw milk is thereby made safe and its keeping power (mainly taxed in the home) is much improved. Your correspondent refers to a manager of a company who is selling pasteurised milk as "Grade A" milk. This would not be possible if the local authority was doing its duty. The rogue in question is running the daily risk of heavy penalties, and the local authority should be put upon his track.

As to Mr. McLachlan's alleged disadvantages of pasteurised milk, I am unable to accept any one of them. Pasteurised milk, he states, "may go bad without curdling if kept for any length of time." Surely no one can dispute that there are lactic acid producing organisms which survive pasteurisation at 145° F. for 30 minutes, and therefore such pasteurised milk always sours before it decomposes. Furthermore, he states that reductase is destroyed by such pasteurisation. I dissent; but supposing that it is so, what is the disadvantage? The ferments found in cows milk mostly gain access in contamination; and those present in uncontaminated milk do not appear to be of value from the standpoints of either digestion or nutrition. The chief enzymes are destroyed, in 30 minutes at about 158°; and it is probable that at 145° the activity of some may be even slightly promoted.

As to the suggestion that pasteurised milk is less digestible than raw milk, I would suggest to your correspondent that he extends his work and research on this matter before he makes up his mind upon it.

I am, Sir, yours faithfully,

London, August 14th, 1926. HENRY KENWOOD.

THE FERTILITY OF THE TUBERCULOUS

To the Editor of THE LANCET.

SIR,—In his recent book, "The Need for Eugenic Reform," Major Leonard Darwin concludes a section on the eugenics of tuberculosis with the following sentence: "Many of these questions are still in doubt, but there can be no doubt that a diminution in the fertility of all tubercular patients would be a blessing to mankind." If this is true it is of evil omen that the fertility of the tuberculous should be as has recently been shown, somewhat above the normal. But is it true? Major Darwin's argument leading to this conclusion is based on two suppositions: that heredity is a very important, almost a dominant, factor in the determination of clinical tuberculosis, and that if this is not the case it must alternatively be assumed that the child of tuberculous parents is excessively liable to become a tuberculous patient by infection.

It is the former reason which weighs with himself. "The most striking fact," he writes, "telling in favour of the power of the hereditary factor is that a higher rate of incidence of this disease generally occurs amongst the children of tuberculous men as compared with that obtaining amongst their wives: for if this fact is to be explained by infection, it means that a man is more likely to infect his child than his wife, a very improbable conclusion."

The possibility—indeed, in view of Krause's work on the lymphatics of the child's as compared with the adult's lung we may say the great probability—that the same human being has less resistance as a child than as an adult has not been taken into account. Another error, all too common among eugenists, into which this most distinguished eugenist has fallen is to assume that natural immunity is the only factor which determines whether or no an infected subject shall become a clinical case. The influence of unusual physical strain, of the quantity of the infecting dose, of the frequency of its repetition—such considerations as these are altogether overlooked. We do not have to believe in the inheritance of acquired characteristics to believe that an individual who has successfully combated clinical tuberculosis may be unusually good stock from which to breed resistant progeny. In the case of tuberculous women there is, of course, a special reason why childbirth is to be feared, but that is altogether aside from the present discussion. It is reasonable to assume, and there is some statistical evidence to support the assumption, that on the whole those patients endowed with low natural immunity die before the consummation of marriage, while those who survive to have children leave to society a legacy of good stock in this particular respect.

And that brings out another weakness of the eugenist's case. Are we to think of tuberculosis resistance as the overwhelmingly important factor in breeding? Man is a complex animal, and it is conceivable, is it not, that there are some individual cases where the genes of the parents contain elements of such solid worth in mental and physical traits that an extra risk of their offspring getting tuberculosis might be worth the taking? As for the argument that the child should be spared the risk of infection from its father, we know first that parental infection, when it does occur, is most often from the mother, that the risk of fatal infection is only slightly greater among children of tuberculous parents than among the general population, and that a well-educated consumptive is a safer person to live with than the many unrecognised carriers of infection who do not know of their complaint.

I am, Sir, yours faithfully,

August 1st, 1926. T.B., M.D.

The Services.

HONORARY SURGEONS TO THE KING.

His Majesty has approved of the appointment of the following to be Honorary Surgeons to the King: Maj.-Gen. H. P. W. Barrow, C.M.G., late R.A.M.C., in succession to Maj.-Gen. C. E. Pollock, late R.A.M.C. (retired); and Maj.-Gen. D. Harvey, C.M.G., late R.A.M.C., in succession to Maj.-Gen. J. R. McMunn, C.B., C.M.G., late R.A.M.C. (retired).

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs. to be Surg. Comdrs.: A. C. Shaw, R. A. Brown and A. C. V. Green.

The following appointments are notified:—Surg. Lt.-Comdrs. P. Lyon to R.N. Hospl. S. Queensferry; L. R. Warburton to R.N. Hospl. Haslar; J. F. Ainley to the *Excellent*; J. R. Brennan to the *Durban*; and E. S. Mellor to the *Yarmouth* for trooping trip. Surg. Lts. C. Godfrey to the *Ark Royal* and A. H. Harkins to the *Broke*.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: D. C. G. Ballingall, H. G. Winter, N. Cantlie, E. A. P. Brock (Prov.), E. Phillips, S. D. Reid, P. J. Ryan and Bt. Maj. E. A. Sutton.

ARMY DENTAL CORPS.

Lt.-Col. J. P. Helliwell to be Col. to complete estab.

ARMY RESERVE OF OFFICERS.

Lt.-Col. W. A. Woodside, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. W. H. P. Hey resigns his commn. and retains his rank with permission to wear the prescribed uniform.

Lt. E. R. Woodroofe to be Capt. (Prov.)

Lt. C. C. P. Anning is secd. under para. 137, T.A. Regns.

W. H. M. Jones and J. W. Murdoch to be Lts.

ROYAL AIR FORCE.

Flying Officer R. S. MacLatchy is transferred to the Reserve, Class D 2.

BRITISH DENTAL HOSPITAL.—The annual report shows that the work of the hospital in providing dental treatment and advice to expectant and nursing mothers and their young children through the medium of clinics established in conjunction with local authorities has been maintained at a high level. A dental clinic for [illegible] child welfare and tuberculous patients is also [illegible] to be opened in [illegible] at the [illegible] School Dental Treatment Centre [illegible] during 192[illegible]

Correspondence.

"Audi alteram partem."

HOSPITAL COMMITTEE VISITORS

To the Editor of THE LANCET.

SIR—The position of members of hospital committees, to whom the duty of visiting the hospital on behalf of the committee is delegated, is too vague I can quite understand that the responsibility must vary to some extent with every institution, that each committee might expect something particular from the visitor, and that each visitor might have his individual interpretation of what was wanted None the less, I think that if hospital visitors could have a general definition of what is required from them, so that they may be useful in reporting to their committees on the conduct of the institutions, they would be usefully served

Want of knowledge as to what is expected of a visitor is a stumbling-block to efficient inspection The visitor is nervous on the one hand lest he should be officious, and on the other lest he should fall short of what is required, while he has no *definite* place in hospital organisation Yet he occupies, or should do so, a place as a definite link between the outside public, as representing a lay committee, and the internal administration of the institution, its medical administrative and nursing services If his work is to be of practical value he should be expected to ask pertinent questions of the secretary or the matron, and if those questions concerned any of the minor officials or nursing staff he ought not to be considered to be exceeding his position. To demand explanations of detail requires tact, but tact should not go so far as to obscure truth

The hospital visitor should know what to observe and to whom he has a right to report needs or omissions, if only that he may obtain explanations, for these might show that the circumstances were not unknown, but that the remedy was not easy to find It would be the visitor's duty to collaborate with the hospital officials to discover the remedy Would it not be possible to suggest the kind of entries that should be made in a visitor's book, so that a record could be kept for the information of the hospital committee as to what the visitor thought required consideration and as to what the hospital officials had to say on the matter? In this way the committee would be informed whether the hospital official responsible in some concrete matter was the matron or the secretary, for at the present time hospital committees must often be in doubt of the particular origin in the administration of the institution of some default brought to their notice from outside As far as I know the relations of the hospital visitor to the secretary, to the matron, and even to his own committee in session are quite vague

A hospital visitor should have a *defined position*, so that he may not fall short of his duties, but particularly so that he should not incur the disagreeable reputation of exceeding them It should be understood that he is on the look-out to suggest improvements in equipment, whether they be merely to raise the standard of comfort or be gravely concerned with the provision for dying patients The amenities of the nurses' home and the administration of the kitchen are matters with which every visitor ought to be familiar He can only be so if he has a position giving him the right to ask questions He can only learn to ask the right questions by the consideration of the replies, and he will only receive useful and detailed replies if it is recognised that he has a right to ask the questions

I am sure that this matter is well worth the attention of hospital committees and hospital medical administrative and nursing services

I am Sir yours faithfully
A VISITOR

August 11th, 1926

SPRUE AND ADDISONIAN ANÆMIA.

To the Editor of THE LANCET

SIR,—In the very interesting and timely article by Dr Manson-Bahr and others in your issue of August 7th there occurs the remark "In Addisonian anæmia, the anæmia is due to disease of the blood-forming organs so that recovery is not dependent on the processes of digestion and assimilation, the glossitis and gastro-intestinal symptoms appear to be secondary to, or to follow on, the primary anæmia" This is a very old view which is, I imagine, generally abandoned to-day in favour of Hunter's theory of hæmolysis in the portal area as the primary factor It is certainly difficult to suppose that the glossitis is due to disease of the bone-marrow

But I only stress this point at the moment in order that the appropriate treatment of both conditions may not be hindered by unproven ætiological theories From the hæmatologist's point of view there is present in both cases an anæmia of hæmolytic type—in other words, hæmolysis is so active that hæmogenesis even when working to the limit (quick work is bad work as we see in the blood) cannot overtake the loss The treatment of this condition usually includes the giving of arsenic If this has some direct action on hæmolysis in Addisonian anæmia it will be as valuable in sprue as in Addisonian anæmia If it only acts in some indirect manner—e g, by inhibiting the growth of organisms in the alimentary canal or by neutralising their toxins—it may still be of use in both cases One is therefore surprised to read concerning arsenic, that "all observers agree upon its harmful effects" I have at the moment under my care a case of sprue in which arsenic seems to be of undoubted value I had another case in which the patient swallowed six days' allowance (54 minims of Fowler's solution) in one day, and it did him so much good that he forthwith returned for more. A week or two back I met an eminent specialist in tropical diseases in consultation over a case of severe sprue-anæmia, and he ordered iron and arsenic with no small emphasis The patient highly approves of the results

Even in Addisonian anæmia, it is possible to give arsenic with so little care that bad results follow, sometimes it is very difficult to avoid bad results, and at others the attacks of gastritis which often appear in this disease are attributed to arsenic But these facts do not outweigh the undoubted benefit in other cases Is it possible that in sprue also arsenic might find a place? The close resemblance between the diseases certainly suggests a careful trial If this has already taken place, I should be glad of any reference to an account of it

Might I also mention that long before the modern lamps were available I was accustomed to use what sunlight Nature provided in the treatment of anæmia and with excellent results This therapeutic weapon has been somewhat discredited of late by the works of unbalanced enthusiasts, but the sprue-anæmia would probably benefit as much as any other

I am, Sir, yours faithfully,
GORDON WARD

Sevenoaks, Kent, August 12th, 1926

PASTEURISATION OF MILK

To the Editor of THE LANCET.

SIR,—Your readers will be in close agreement with your correspondent, Mr T McLachlan, when he states that whenever pasteurised milk is sold to the public the purchaser should be informed of the fact This is the present practice of the leading London firms of distributors, in so far as bottled pasteurised milk is concerned For instance, every bottle of milk distributed by the dairies controlled by United Dairies, Limited, has the word "pasteurised" printed on the cap of the bottle It is obviously impossible to label the milk which is distributed in cans—a rapidly decreasing quantity. There is no trade desire to hide the fact of pasteurisation for it is recognised that in large towns deriving milk from long distances such pasteurisation is greatly in the public interest, for it ensures that the excellent collection of etchings and prints, the Ceramic Art Society and similar organisations gained much by his support For many years he enjoyed the friendship of Mr Arnold Bennett, and is said to have been the original of the Dr Stirling, of Bleakridge, who figures in that author's novels of the Five Towns

Medical News.

Final F R C S Eng Examination —Courses of instruction for the Final Examination for the Fellowship of the Royal College of Surgeons of England will commence on Wednesday, Sept 1st, at Guy's Hospital Medical School and at the London Hospital Medical College The fee in either case is 20 guineas, operative surgery 5 guineas extra Further particulars in our advertisement columns

University of Sydney Chair of Psychiatry —The Senate invites applications for the Chair of Psychiatry, of which we publish particulars in our advertisement columns The professor will be expected to enter on his duties on March 1st, 1927, and applications from the United Kingdom should be sent in proper form to the Agent-General for New South Wales before Sept 15th Applicants, it is stated, should have been trained in a mental hospital, and should be interested primarily in clinical rather than pathological work

National Institute for the Blind —The voluminous and well-illustrated report for the year ended March 31st, 1926, is a record of steady constructive progress It is, in fact, a small encyclopædia dealing with all aspects of the blind community The report has been compiled on new lines The first part is an account of the actual work accomplished during the year, including details of the Institute's endeavour to link up national and local work and of the scheme now adopted, with the approval of the Ministry of Health, to ensure that the distinctions "national" and "local" shall indicate relationship and not rivalry The second part is divided into sections each illustrative of some phase of work for the blind

Hospital Treatment of Encephalitis Sequels in Scotland —Encephalitis lethargica has been notifiable in Scotland since December of last year, and the disease in its acute stage has been dealt with in the hospitals provided for the treatment of infectious disease in general. The subsequent care of bedrid patients who still require special treatment and nursing is providing a difficult problem The Parish Council of Glasgow has now allotted 40 to 50 beds to these cases in a separate block of the Stobhill Hospital with a daily charge of 7*s* provisionally fixed Less suitable cases will be gradually eliminated so as to leave only those who urgently require the benefits of institutional care At the hospital the services of a mental specialist and of the council's pathologist will be available

Fellowship of Medicine and Post-Graduate Medical Association —On Monday, August 23rd, Queen Mary's Hospital will begin a two weeks' intensive course in medicine, surgery, and the specialties, this will include operations, lectures, and demonstrations in all departments of the hospital, which will be thrown open for the whole of each day There is a well-equipped pathological department and new maternity wards Every week the City of London Maternity Hospital holds a special course in obstetrics, instruction being given during the whole day. Personal application for this course must be made to the Secretary of the Fellowship During September arrangements will be as follows An intensive course covering all branches of medicine, surgery, and the specialties will be given at Westminster Hospital during the whole of each day from Sept 20th to Oct 2nd On Sept 13th the Infants Hospital will begin a course in the diseases of infants, lasting for two weeks, there will be lectures and demonstrations each afternoon and a visit has been arranged to Thavies Inn V D Centre on the Sunday At the Royal Free Hospital Dr C B Heald will give four lecture-demonstrations in treatment by electrotherapy on Wednesday, Sept 22nd, and the three succeeding Wednesdays, at 5 15 P M A course will be given at the Central London Ophthalmic Hospital from Sept 6th to Oct 2nd instruction being given every afternoon The Bethlem Royal Hospital staff will hold a series of lecture-demonstrations on Tuesdays and Saturdays at 11 A M from Sept 2nd to Oct 2nd An all-day course in orthopædics will be held at the Royal National Orthopædic Hospital from Sept 20th to Oct 2nd, covering all branches of the subject. Copies of all syllabuses, of the General Course programme, and of the *Post Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1 Wimpole street, London, W 1

Major Henry Edward Sutherland Richards, Chief Medical and Health Officer, has been appointed a member of the Executive Council of the Island of Grenada

The address of the Panel Committee for the County of London is now 17–18, Russell-square, W C 1 Telephone number Museum 9912

Dr J B Hurry, the founder of the Michael Foster studentship in physiology at the University of Cambridge, has increased its endowment by £100

Dr L J Witts, of the University of Manchester, has been elected to the John Lucas Walker studentship in pathology at Cambridge for three years, and Mr J O W Bland, Jesus College, to a second studentship for one year

Mr Basil Graves is to give an address on the Surgery of Senile Cataract at the thirty-first annual congress of the American Academy of Ophthalmology and Oto-Laryngology, which opens on Sept. 13th at Colorado Springs.

Dr Karl Henschen, who has been appointed to succeed the late Prof Hotz in the Chair of Surgery at the University of Basle, is surgeon to the Cantonal Hospital at St. Gall with the title of Professor at the University of Zurich

Princess Mary at Hartlepool Hospital.—On August 11th Princess Mary opened a new wing of this hospital named the Morison Wing, in honour of the late Dr A. E Morison, an energetic worker for the institution The new building has cost £10,000

The Laennec Centenary —On August 12th the hundredth anniversary of the death of Laënnec was celebrated at his native village of Ploaré, Finistère, Brittany. The French medical profession was strongly represented and a panegyric was delivered in Ploare church. Next December the centenary will be celebrated in Paris

Messrs Chapman and Hall have been preparing a book on "The Theory and Practice of Radiology," by Dr Bernard Leggett, but owing to a recent fire at the Whitefriars Press the whole work, almost completed, has been destroyed, and it will therefore be some months before it can be published.

The late Dr W A M Garry —Dr William Alfred MacMahon Garry, who died at his home in Liverpool on August 7th at the age of 62, was an Irishman by birth and studied medicine at Queen's College, Galway, and at the Catholic University, Dublin. Before settling in Liverpool, where he practised for 40 years, he was a resident in the Coombe Lying-in Hospital, Dublin, and assistant medical officer at the Salford Hospital. Dr Garry was especially well known to the Roman Catholic community and much of his time and professional skill was given to charitable causes He was hon physician to the House of Providence, Aigburth, and visiting physician at the Priory, Allerton, a home for feeble-minded and mentally defective children.

The Causation of Gout —The 115th annual report of the Devonshire Hospital and Buxton Bath Charity covers the period from Jan 1st, 1925, to March 31st, 1926 The report of the bacteriological department states that numerous determinations of the amount of calcium in the blood serum of gout cases were made, and that the results showed quite definitely that "there is no association of hypercalcæmia with uncomplicated gout"—the direct opposite of the results obtained in the small Bath series of Coates and Raiment It is suggested that some other factor, possibly connected with the parathyroid, accounted for the abnormal values obtained in the Bath series The blood analyses of gout cases indicate that, with the exception of certain nephritic cases, the carbonic acid content of the plasma in gout is not abnormally low and that a general lack of base in the circulating blood cannot be a factor in the deposition of uric acid in the tissues. A special report is being prepared.

The late Dr K C Gimson —Dr Karl Carwardine Gimson, of Witham, who died suddenly on August 3rd, was a son of the late Dr Gimson Gimson of Witham, and was born in 1866 He received his medical education at Cambridge and St Bartholomew's Hospital graduating at Cambridge in 1891 After making several voyages to the Far East as ship's surgeon he joined his father in practice. When his father died 26 years ago Dr K C Gimson with one of his two medical brothers took over the practice which became very large Whilst his brother was away at the war he carried on the work by himself and in addition to his ordinary duties, acted as medical officer to the temporary war hospital at Bridge Home He was a keen sportsman shooting cricket fishing, and golf being his principal recreations and was a generous supporter of any kind of work for the benefit of his fellow townsmen Dr Gimson was a bachelor

Obituary.

ROBERT HENRY COLE, M D, F R C P LOND

THE death of Dr R. H Cole, which we recorded last week, removes a much respected authority on mental disease from the ranks of London consulting physicians

Robert Henry Cole was the eldest son of the late Mr R C Cole, of Ealing, and was born in 1866 He was destined for the Civil Service, and for a short time worked as a clerk in the India Office. He qualified in medicine nevertheless, at the age of 23, and after holding a house appointment at St Mary's Hospital, took up the special study of psychiatry to which the rest of his life was devoted Thirty-six years of association with Moorcroft House began with his appointment as resident physician soon after leaving St Mary's, and in the years during which he held this post he won a high reputation for clinical skill and for the helpful care which he bestowed on his patients He always made remarkably good use of his time; he read a great deal and he was keenly interested in his specialty. In 1907 he began to engage exclusively in consulting practice, and soon afterwards was appointed physician for mental diseases to St Mary's Hospital and lecturer in the medical school. He later became an examiner in mental diseases and psychology in the University of London, and held several other appointments, including those of Home Office Visitor to the State Inebriate Reformatory at Aylesbury, visitor to the approved institutions for the mentally defective in Middlesex, and lecturer in mental diseases at Bethlem Royal Hospital His considerable experience is embodied in the well-known text-book on mental diseases which he wrote—now in its third edition—whilst his knowledge of, and sympathy with, modern views on psychology and treatment were shown in his presidential address to the Section of Psychiatry of the Royal Society of Medicine recently published in our columns [1] This thoughtful comment on the progress of the last 30 or 40 years is evidence of a wide outlook, and is written in his characteristic style

For the Royal Medico-Psychological Association Dr Cole did a great deal of painstaking work At the time of his death he was chairman of the Parliamentary Committee of the Association, in which office his acquaintance with the legal relations of insanity were very valuable Intimate knowledge of the history of lunacy legislation enabled him to offer wise counsel, and the Association owes a great deal to him "His place" writes one of his colleagues, "will be hard to fill Those who knew him will miss his genial and kindly presence Unchanging loyalty was the most striking feature of his friendship He always gave unsparingly of his best, and was accustomed to take immense pains with his patients, on whose behalf he laboured without counting the cost in time and trouble And his younger colleagues would seek his advice constantly, knowing that he would appreciate their problems and help them in every possible way"

Dr Cole leaves a widow, a son, and a daughter

JOHN FRANCIS HALL-EDWARDS,
L R C P EDIN, D M R E CAMB, F R S EDIN

Dr J. F Hall-Edwards, who died at Edgbaston on August 15th, was one of the first medical men in this country to use X rays, and like many others who have worked with unknown materials for the advancement of knowledge, he had to pay heavily for an adventure which has benefited other people In the first few years of this century he contracted dermatitis by exposure to X rays, but his courage and enthusiasm were such that in spite of increasing disability he carried on with his work until recently

The son of Dr John Edwards, of Sparkbrook, John Hall-Edwards was born in 1858 and was educated at King Edward's School and at Queen's College, Birmingham, where he acted as assistant demonstrator in physiology for two years At the age of 27 he took the diploma of L R C P Edin, and settled in practice at Moseley His hobby was photography, and he soon became a leading light in the local photographic societies, publishing papers on microphotography and kindred subjects When, in 1896, Rontgen published his discovery of X rays, Hall-Edwards brought a well-prepared mind to the study of their application to medicine and surgery He was soon writing articles on their use, and in 1889 was appointed surgeon-radiographer to the General Hospital and other Birmingham institutions In the following year he went out to South Africa and successfully organised a radiological service for the Imperial Yeomanry Hospitals at Deelfontein and Pretoria At this time, unfortunately, no precautions were taken against X ray burns, and Hall-Edwards began to suffer from their effects soon after his return The dermatitis was progressive and after six years of suffering he had his left arm amputated, later he lost four fingers of the right hand as well In 1908 his sacrifices in the furtherance of radiology were recognised by the grant of a Civil List pension

The outbreak of the late war found Hall-Edwards ready and anxious for further service, and he did good work as radiologist to the 1st and 2nd Birmingham War Hospitals and the Monyhull Military Hospital, he held a temporary commission as Major in the Royal Army Medical Corps and was twice mentioned. At the end of the war he continued to practise as radiologist in Birmingham and even took the diploma of radiological medicine at the University of Cambridge in 1920 Two years later the Carnegie Hero Trust medallion was awarded to him, and in the present year he was elected an honorary member of the British Medical Association He was also at one time *President of the British Electro*-therapeutic Society, and editor of *Archives of the Rontgen Ray* Enthusiasm for his work, however, did not make him a man of one idea After the war he served usefully on the corporation of the city of Birmingham and was a member of the Art Gallery Committee Originally he had intended to be an artist himself, and during the last few years he took up painting again, holding the brushes between the thumb of his right hand and an artificial finger Some of his work was shown at the exhibition by medical men at the Royal Society of Medicine in 1924

JOHN RUSSELL, O B E, M B. ABERD

Dr John Russell, who died on August 10th at the age of 64, was for many years one of the best-known medical men in the Potteries, he practised in Burslem until last year, when he retired to Grantown-on-Spey Born at Insch in Aberdeenshire, he was educated at the University of Aberdeen, where he graduated in arts in 1883 and in medicine three years later He also studied in Dublin Forty years ago he went to Burslem and soon established a large private practice and entered upon many public appointments At the time of his death he was consulting physician to the North Staffordshire (now the Royal) Infirmary and to the Haywood Hospital, Burslem, and *for many* years he was public vaccinator, police surgeon, and medical officer of health for *the* Burslem district. Several pottery manufacturers appointed him their adviser on industrial diseases He was at one time President of the North Staffordshire Medical Society and of the Staffordshire branch of the British Medical Association and *as assistant* county director of the British Red *Cross* Society did good work during the war in connexion with convoys of wounded to the *local hospitals For* this and other public services he was made an officer of the Order of the British Empire Dr Russell's life in Burslem was full of interests For some time he was a captain in the Volunteers, he was keen on every kind of sport, and was a popular member of local clubs and societies He read extensively, had a good library and an excellent collection of etchings and prints: the Ceramic Art Society and similar organisations gained much by his support For many years he enjoyed the friendship of Mr. Arnold Bennett and is said to have been the original of the Dr. Stirling, of Bleakridge who figures in that author's novels of the Five Towns.

Medical News.

FINAL F R C S ENG EXAMINATION.—Courses of instruction for the Final Examination for the Fellowship of the Royal College of Surgeons of England will commence on Wednesday, Sept 1st, at Guy's Hospital Medical School and at the London Hospital Medical College. The fee in either case is 20 guineas, operative surgery 5 guineas extra. Further particulars in our advertisement columns.

UNIVERSITY OF SYDNEY: CHAIR OF PSYCHIATRY — The Senate invites applications for the Chair of Psychiatry, of which we publish particulars in our advertisement columns. The professor will be expected to enter on his duties on March 1st, 1927, and applications from the United Kingdom should be sent in proper form to the Agent-General for New South Wales before Sept. 15th. Applicants, it is stated, should have been trained in a mental hospital, and should be interested primarily in clinical rather than pathological work.

NATIONAL INSTITUTE FOR THE BLIND —The voluminous and well-illustrated report for the year ended March 31st, 1926, is a record of steady constructive progress. It is, in fact, a small encyclopædia dealing with all aspects of the blind community. The report has been compiled on new lines. The first part is an account of the actual work accomplished during the year, including details of the Institute's endeavour to link up national and local work and of the scheme now adopted, with the approval of the Ministry of Health, to ensure that the distinctions "national" and "local" shall indicate relationship and not rivalry. The second part is divided into sections each illustrative of some phase of work for the blind.

HOSPITAL TREATMENT OF ENCEPHALITIS SEQUELS IN SCOTLAND —Encephalitis lethargica has been notifiable in Scotland since December of last year, and the disease in its acute stage has been dealt with in the hospitals provided for the treatment of infectious disease in general. The subsequent care of bedrid patients who still require special treatment and nursing is providing a difficult problem. The Parish Council of Glasgow has now allotted 40 to 50 beds to these cases in a separate block of the Stobhill Hospital with a daily charge of 7s provisionally fixed. Less suitable cases will be gradually eliminated so as to leave only those who urgently require the benefits of institutional care. At the hospital the services of a mental specialist and of the council's pathologist will be available.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Monday, August 23rd, Queen Mary's Hospital will begin a two weeks' intensive course in medicine, surgery, and the specialties; this will include operations lectures, and demonstrations in all departments of the hospital, which will be thrown open for the whole of each day. There is a well-equipped pathological department and new maternity wards. Every week the City of London Maternity Hospital holds a special course in obstetrics, instruction being given during the whole day Personal application for this course must be made to the Secretary *of* the Fellowship During September arrangements will be as follows: An intensive course covering all branches of medicine, surgery and the specialties will be given at Westminster Hospital during the whole of each day from Sept. 20th to Oct. 2nd. On Sept. 13th the Infants Hospital will begin a course in the diseases of infants, lasting for two weeks: there will be lectures and demonstrations each afternoon and a visit has been arranged to Thames Inn V.D. Centre on the Sunday At the Royal Free Hospital Dr. C B Heald will give four lecture-demonstrations in treatment by electrotherapy on Wednesday, Sept. 22nd, and the three succeeding Wednesdays, at 5 15 P.M. A course will be given at the Central London Ophthalmic Hospital from Sept. 6th to Oct. 2nd, instruction being given every afternoon. The Bethlem Royal Hospital staff will hold a series of lecture-demonstrations on Tuesdays and Saturdays at 11 A.M. from Sept. 2nd to Oct. 2nd. An all-day course in orthopædics will be held at the Royal National Orthopædic Hospital from Sept. 20th to Oct. 2nd, covering all branches of the subject. Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1 Wimpole-street London, W 1.

Major Henry Edward Sutherland Richards Chief Medical and Health Officer, has been appointed a member of the Executive Council of the Island of Grenada.

THE address of the Panel Committee for the County of London is now 17–18, Russell-square, W.C. 1. Telephone number, Museum 9942

Dr. J. B. Hurry, the founder of the Michael Foster studentship in physiology at the University of Cambridge, has increased its endowment by £100

Dr L J Witts, of the University of Manchester, has been elected to the John Lucas Walker studentship in pathology at Cambridge for three years, and Mr. J. O W. Bland, Jesus College to a second studentship for one year

Mr. Basil Graves is to give an address on the Surgery of Senile Cataract at the thirty-first annual congress of the American Academy of Ophthalmology and Oto-Laryngology, which opens on Sept. 13th at Colorado Springs

Dr. Karl Henschen, who has been appointed to succeed the late Prof. Hotz in the Chair of Surgery at the University of Basle, is surgeon to the Cantonal Hospital at St. Gall with the title of Professor at the University of Zurich.

PRINCESS MARY AT HARTLEPOOL HOSPITAL.—On August 11th Princess Mary opened a new wing of this hospital named the Morison Wing, in honour of the late Dr. A. E. Morison, an energetic worker for the institution. The new building has cost £10,000.

THE LAENNEC CENTENARY.—On August 12th the hundredth anniversary of the death of Laënnec was celebrated at his native village of Ploaré, Finistère, Brittany. The French medical profession was strongly represented and a panegyric was delivered in Ploaré church. Next December the centenary will be celebrated in Paris.

Messrs. Chapman and Hall have been preparing a book on "The Theory and Practice of Radiology," by Dr Bernard Leggett, but owing to a recent fire at the Whitefriars Press the whole work, almost completed, has been destroyed, and it will therefore be some months before it can be published.

THE LATE DR. W. A. M. GARRY.—Dr. William Alfred MacMahon Garry, who died at his home in Liverpool on August 7th at the age of 62, was an Irishman by birth and studied medicine at Queen's College, Galway, and at the Catholic University, Dublin. Before settling in Liverpool, where he practised for 40 years, he was a resident in the Coombe Lying-in Hospital, Dublin, and assistant medical officer at the Salford Hospital. Dr. Garry was especially well known to the Roman Catholic community and much of his time and professional skill was given to charitable causes. He was hon. physician to the House of Providence, Aigburth, and visiting physician at the Priory, Allerton, a home for feeble-minded and mentally defective children.

THE CAUSATION OF GOUT.—The 115th annual report of the Devonshire Hospital and Buxton Bath Charity covers the period from Jan. 1st, 1925, to March 31st, 1926. The report of the bacteriological department states that numerous determinations of the amount *of calcium* in the blood serum of gout cases were made, and that the results showed quite definitely that "there is no association of hypercalcæmia with uncomplicated gout"—the direct opposite of the results obtained in the small Bath series of Coates and Raiment. It is suggested that some other factor, possibly connected with the parathyroid, accounted for the abnormal values obtained in the Bath series. The blood analyses of gout cases indicate that, with the exception of certain nephritic cases, the carbonic acid content of the plasma in gout is not abnormally low and that a general lack of base in the circulating blood cannot be a factor in the deposition of uric acid in the tissues. A special report is being prepared.

THE LATE DR. K. C GIMSON.—Dr. Karl Carwardine Gimson, of Witham, who died suddenly on August 3rd, was a son of the late Dr. Gimson Gimson, of Witham, and was born in 1866 He received his medical education at Cambridge and St. Bartholomew's Hospital, graduating at Cambridge in 1891. After making several voyages to the Far East as ship's surgeon he joined his father in practice. When his father died 26 years ago Dr. K. C. Gimson, with one of his two medical brothers took over the practice, which became very large. Whilst his brother was away at the war he carried on the work by himself, and, in addition to his ordinary duties acted as medical officer to the temporary war hospital at Bridge Home. He was a keen sportsman, shooting cricket, fishing, and golf being his principal recreations, and was a generous supporter of any kind of work for the benefit of his fellow-townsmen. Dr. Gimson was a bachelor.

Notes, Comments, and Abstracts.

MEDICINE IN MEXICO

By Frances E Smith, M R C S Eng

During a private visit to Mexico last year I saw a good deal of the condition of medical practice there, which may be worth describing

The country has every kind of climate, from tropical on the coast to temperate further inland, and away from the populous areas it is very wild indeed Though good medical advice is to be had in the towns it is usually unobtainable elsewhere The best medical treatment is found in the capital, Mexico City, conditions in which I shall describe first.

Mexico City

There are several hospitals, the most modern being the Cowdray Sanatorium, also known as the English Hospital This is endowed by Lord and Lady Cowdray and was completed some three years ago It is situated in beautiful and healthy country just outside the city and has accommodation for 50 patients The equipment includes an isolation ward, laboratories, two theatres—one of them an obstetric theatre—and excellent quarters for the nursing staff The matron is British and the nurses British or American The Trust Deed provides for the appointment of a resident medical officer, but it was decided to do without one All the patients are private cases ; they are attended by their own doctors, and most of them have their own rooms or suites Emergency cases are in the hands of the matron and her staff until the particular surgeon arrives There are two wards for poor patients, the cost of whose maintenance is defrayed by societies The charges for room and board vary from $6 Mex. a day for a bed in a common ward to $50 a day for a suite ($1 Mex =1 peso, worth about 2*s*) The average charge is between $10 and $12 per day The chief other hospitals are the American, the French, and three native hospitals, one of which is under the Red Cross The American and French hospitals are in what were once large private houses, and the American has a pathological department which is at the disposal of practitioners One of the native hospitals has been in existence since the time of Cortes who conquered Mexico in 1521

Private practice is carried on in much the same way as in England There are large numbers of Mexican doctors, graduates of the University of Mexico, many of whom have had European or American experience, are competent and have large practices The foreigners are mostly American, but there are also English, French, German, and Spanish practitioners The city has numerous good surgeons, specialists, and dentists Fees are adjusted to the means of the patients A prosperous business man pays $5 Mex. for a visit to the consulting-room and $10 if the doctor comes to the house (These fees were paid to a well-known American practitioner, but I am told that Mexican doctors do not charge so much.) Foreigners generally go to a doctor of their own nationality In comparing these fees with those in England it should be remembered that the cost of living in Mexico just now is roughly twice as high as in the United Kingdom. Mexico City is, moreover, a prosperous place and sometimes large sums are asked and given A high official of a commercial company was charged $1500 Mex by a foreign doctor for attending a case of typhoid. Advertising by members of the medical profession is common, it is chiefly done through the newspapers or by notices in hotels Foreigners are required to take the examinations of the University of Mexico before being allowed to practise

The Red Cross Society, supported by public subscription, seems to be well organised , it has its own hospital, and ambulances arrive promptly on the scene of an accident I saw an aeroplane crash in a field well outside the city, and within five minutes there were present two ambulances and three carloads of police A small boy was operated on at the hospital within 20 minutes of having his leg crushed in the street

Health propaganda is carried on freely, and at times whole pages of the newspapers are devoted to suitable subjects, such as trachoma

Charlatanism is rife. Chiropractors, osteopaths, naturopaths, and others are found everywhere. Their nationality varies , many have had to leave the United States and find in Mexico a lucrative field. They advertise in most of the periodicals and newspapers, and by means of pamphlets distributed in the streets

Health of Poor People

The native Mexican leads a very primitive life He lives with his family in a shack of wood or leaves whose floor is the bare earth His chief possessions are the clothes on his back, his blanket, a gun, a dog (starving and mangy), and a few chickens The family has also some cooking utensils and a charcoal stove Maize is grown around the hut and beans and chiles from the local market complete the staple diet The sunny climate makes this sort of life possible, but great hardships are undergone during cold or rainy weather

Infant mortality is high Although the average Mexican adores his children, the babies are fed unwisely on chiles beans, hot sauces and other adult food, much of which is greasy As a result, they suffer so much from malnutrition and digestive disturbances that they are usually puny creatures, especially in the towns Exposure to cold occurs during the rainy season (July to September), and sometimes during the winter months The results are often disastrous, children, and even adults, being found dead after a cold spell During these times the mortality from pneumonia is very high , the Mexican shows a very poor resistance to pneumonia and tuberculosis, and in Mexico City a common cold often ends in pneumonia, both amongst natives and foreigners

Digestive troubles are very common everywhere The chief cause is general over-eating of heavy rich foods, sweet things being much liked Another cause is irregular eating , a walk through the streets is punctuated by small purchases of candies, pastries, and fruits, which are sold everywhere at little stalls

Deformities of all kinds are seen Most deformed people are beggars, and begging is a profession. It is said that babies are prevented from having treatment, and even deliberately deformed, in order to be made beggars, and I have seen the most extreme cases of all kinds—old infantile paralyses, Little's disease, spinal curvatures, and all forms of tuberculous deformities—such as are rarely to be found in England Beggars are everywhere—in the streets, outside churches, and on the country roads Many are unable to use crutches, and drag themselves along very efficiently on their knees and hands protected by guards of wood and leather Most of them are well cared for and often their cotton clothes are spotlessly white Blindness, scars, wounds, and amputation stumps are all exploited

Rural Mexico

San Luis Potosi, Monterey, Orizaba, and Tampico are the principal towns outside Mexico City itself, and the above remarks may be said in general to apply to them There are few hospitals, however, in these towns and few in the "hot country," though Tampico has two and there are a certain number in connexion with industrial concerns Private practice exists everywhere, and in the larger towns there are English and American doctors as well as Mexican. Malaria is common all along the coast and sometimes bad cases have to go up to Mexico City to obtain relief from the repeated attacks Yellow fever occurs in the more southern regions, including the Isthmus of Tehuantepec and Yucatan, and typhoid is also very prevalent

Snakes, tarantulas, and alacrans abound everywhere. Chiggers (sand fleas) cause a lot of trouble, the female penetrating under the skin of the foot or hand, especially at the nails, and producing intense irritation Unless the patient is prepared to wait until the insect sloughs out, it is best removed by enucleation, which is often neatly done by native women, who fill up the hole left with tobacco ash

The plain of Mexico on which the capital is situated is about 7500 feet above sea-level The effects of the altitude on newcomers and inhabitants vary, but severe symptoms are uncommon, the most usual being drowsiness, headache, shortness of breath on exertion, nausea, and indigestion. A person usually experiences one or two of these symptoms on arrival, but they pass off after a few days Rowing and football are very strenuous games at this altitude and races at a recent regatta were rowed over a shorter course than at home

ILLUMINATION AND VISUAL ACUITY

A COMMITTEE of the Medical Research Council is at work studying problems involving questions of vision Their first task has been to publish an analysis of the more recent work upon the relation of illumination and visual capacities, prepared by Mr R J Lythgoe (H M Stationery Office 2*s* 6*d*) The works analysed are monographs by European or American writers, and their subjects include the influence of different intensities of illumination on visual acuity, the effect of varying the character of illumination on visual acuity, the discrimination of differences of brightness adaptation as a factor in visual discrimination, the influence of lateral illumination including "glare" on visual judgments, the speed of retinal impression, the influence of illumination on the discrimination of colours, and lastly visual fatigue The utility of the brochure consists in its concise summaries of recent work on all these subjects and a good bibliography Its avowed object is not to present a final pronouncement on any of these subjects but to afford help to other workers

MEDICAL REGISTRATION IN IRELAND —An order has been made by the Executive Council of the Irish Free State continuing the existing arrangements for medical registration for the period of one month.

CENTENARY OF THE COOMBE LYING-IN HOSPITAL, DUBLIN —The centenary of the Coombe Hospital will be celebrated from Tuesday, Sept 14th, to Friday, Sept. 17th Dr Louis Cassidy is acting as hon secretary and will be glad to send further information to those interested His address is 6, Kildare-street, Dublin We hope later to publish details of the programme

RAILWAYMEN SUPPORT HOSPITALS —The majority of the staff of the London, Midland and Scottish Railway, comprising about a quarter of a million workers, contribute 2*d* per week to the L.M S Hospital Fund , this is deducted through the paybills The directors of the company augment the sum by another 1*d* , and a total amount of £136,000 was by these means contributed last year The privileges of membership include admission to any hospital in the country for the member himself and for his wife and children. In addition, the railwaymen (of all companies) maintain seven convalescent homes of their own. The railway directors have now handed over the management of the fund to the staff, and on the committee of 13 they have only one representative.

THE LATE DR O J CAREGAN —Dr Owen Joseph Caregan, who died on August 7th at his home in Ormskirk, was a native of Liverpool and studied at the Liverpool School of Medicine and at the University College He qualified L R C P & S Edin in 1892, and was for a time junior house surgeon at Bootle Borough Hospital. After going as assistant to the late Dr Walsh, of Ormskirk, he settled in that town and soon had a large practice there as well as in West Lancashire generally, being appointed surgeon to the Ormskirk Cottage Hospital, certifying factory surgeon, and medical referee to several assurance companies He worked in the district for over 30 years, and although not in good health continued to practise up till the week of his death. Dr. Caregan was 64 years of age and leaves a widow

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, W

MONDAY, August 23rd, to SATURDAY, August 28th —QUEEN'S HOSPITAL FOR CHILDREN, Hackney road, Bethnal Green, E Course in Diseases of Children. Lectures and demonstrations all day, and work available in all departments (second week) —QUEEN MARY'S HOSPITAL, Stratford, E Course in Medicine, Surgery, and the Specialties Lectures and demonstrations all day for two weeks in all departments Operations Further particulars from the Secretary of the Fellowship

POST-GRADUATE HOSTEL, Imperial Hotel, Russell square, W C

TUESDAY, August 24th —9 P M Mr W McAdam Eccles will open a discussion on When not to Operate for Hernia

THURSDAY —9 P M , Mr R J McNeill Love will open a discussion on the Treatment of Acute Appendicitis

Appointments.

JONES, D W , M R C S , L R.C P Lond., has been appointed one of the Medical Referees under the Workmen's Compensation Act for the County Courts Districts of Pocklington, Selby, Beverley, Bridlington, Goole, Great Driffield, Howden, and Kingston-upon-Hull

SLOT, GERALD, M D , M R C P Lond , D.P H., Honorary Physician to the Royal Hospital, Richmond

THIERENS, MILDRED M., M B , Ch B Liverp , Asst Medical Officer of Health for Maternity and Child Welfare, Batley

WEST, B A , M D Belf , D P H , Certifying Surgeon under the Factory and Workshop Acts for the Epperstone District of the County of Nottingham

Vacancies.

For further information refer to the advertisement columns

Birkenhead and Wirral Children's Hospital, Woodchurch-road —H S £100

Birmingham, Queen's Hospital —H P At rate of £70

Bootle Borough Hospital —Sen M O and two Jun M O's £150 and £125 respectively

Bradford, Municipal General Hospital, St Luke's —H P.'s and H S 's Each at rate of £200

Bridgend, Glamorgan County Mental Hospital —Jun Asst M.O £350

Brighton, New Sussex Hospital, Windlesham road —H S At rate of £50.

Bristol General Hospital —H P.'s, H S 's, &c Each at rate of £80

Bristol Royal Infirmary —H P 's, H S 's, &c Each at rate of £80

Bristol University —Asst to Professor of Surgery £400

Cardiff, Prince of Wales's Hospital —H S £100

City of London Hospital for Diseases of Heart and Lungs, Victoria-park, E —Asst Tuberculosis O £600

Edinburgh, Royal Mental Hospital, Morningside —Asst M O £350

Essex, Administrative County of —Asst County M O H £600

Halifax County Borough —Tuberculosis O £650

Infants Hospital, Vincent-square, Westminster —Jun Anæsth.

Leicester Royal Infirmary —H P At rate of £120

Leicestershire County Council —County M.O H £1200

Maidstone, Kent County Mental Hospital.—Asst M O £300

Manchester, Royal Children's Hospital, Gartside street —Asst. M.O At rate of £150

Manchester, Royal Children's Hospital, Pendlebury —Res M.O At rate of £120

Manchester Royal Eye Hospital —Jun H S £120

Mildmay Mission Hospital, Austin street, Bethnal Green, E —Hon Dental S

Oxford, Radcliffe Infirmary and County Hospital —H.P and Cas H S Each at rate of £120

Poplar Hospital for Accidents, East India Dock road, Poplar, E —Second Res O £175

Queen's Hospital for Children, Hackney road, E —P for Skin Dept Also H P and H S Each at rate of £100

Royal National Orthopædic Hospital, 234, Great Portland street, W —H S At rate of £150

St Mary's Hospital, W —Asst M O for X Ray Dept

Sheffield University (Dept of Pathology) —Asst Bacteriologist £300

Sydney University, New South Wales, Australia —Professorship of Psychiatry £1100

Taunton Rural District, &c —M O H &c £800

West London Hospital, Hammersmith road, W —One H P and Two H S 's Each at rate of £100

Willesden General Hospital —Cas O. At rate of £120

Wolverhampton and Staffordshire Hospital,—H S At rate of £150

Worcester General Infirmary —Jun. Res M O £120

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Burntisland (Fifeshire), and Tibshelf (Derbyshire)

Births, Marriages, and Deaths.

BIRTHS

BEAUMONT —On August 11th, at Welbeck street, the wife of Dr Beaumont, of Swains lane, Highgate, of a son

COOK —On August 11th, at "Marven," Uplyme, Lyme Regis, the wife of Dr P N Cook, of a daughter

CRANSTOUN —On August 12th, at Perry Hill, Worplesdon, the wife of Dr G Cranstoun, of a son

DUFFUS —On August 7th at a nursing home, Aberdeen, the wife of Dr Allan A. Duffus, Gilling Lodge, Watford, Herts, of a son

FLEMING —On August 9th, at Red House, Staines road, Bedfont Middlesex, Dr Muriel Fleming, the wife of Dr Arthur Fleming, of a son

MARSHALL.—On August 7th, at The Grove, Heacham, Norfolk, the wife of Philip Sydney Marshall, M R.C S , D P H., of a daughter

MARRIAGES

NOAKES—GERARD —On July 21st at The Oratory of the Sacred Heart, Bournemouth, by the Rev Joseph Flynn (with Nuptial Mass), Basil Henry Noakes, of The Rest Brockenhurst, to Mary Josephine Gerard (Minnie), of Devonshire House, Bournemouth

ROWAND—NAISMITH.—On August 4th, at the Parish Church, Fortingal, Andrew Rowand, M D , James Mackenzie Institute, St Andrews, to Edith Mary, widow of W J Naismith, M D , D S O , and youngest daughter of the late Prof. W R Sanders, Edinburgh University

DEATHS

CALLENDER —On August 14th, at Inverard, Sidcup, Kent, Thomas Marshall Callender M D , F R C S E , aged 52

HARRIS —On August 12th, at Frome, Andrew Harris, M B E., F R C S I , aged 63 years

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

INDEX TO "THE LANCET," VOL I, 1926

THE Index and Title-page to Vol I, 1926, which was completed with the issue of June 26th, is now ready A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now

STUDENTS' GUIDE—SESSION 1926-1927.

THE scheme upon which the Students' Number of THE LANCET is constructed will make it easy, we hope, for all who consult it to find what they seek The General Council of Medical Education and Registration is the controlling authority of all the medical and dental education of the country, and its responsibility for the upkeep of the Medical Register and for the maintenance of the examination standard is first explained.

But the student has to be taught as well as examined, and as the systems under which instruction can be obtained do not conform to one pattern, the various curricula are described in detail, and under their respective headings the necessary information will be found concerning the facilities for medical study offered at the different teaching centres of the United Kingdom The regulations for the examinations, both preliminary and professional, at these centres are set out so that the student desiring to obtain a medical degree from any university, or a diploma from any medical corporation, may ascertain the course of clinical instruction and the conditions under which submission for examination has to take place The metropolitan medical schools and hospitals are grouped under the University of London, of which they are constituent bodies, although their educational opportunities are offered to students of other universities as well as to those seeking the qualifications of the medical corporations A similar plan is adopted in dealing with the provincial universities, the hospitals in direct connexion with which are described with the universities; the hospitals may not be official schools of the universities, but they supply an integral section of the teaching required.

Upon securing degrees or diplomas admission to the Register follows, and greater education begins The prudent young doctor already knows what he or she desires to make the next step, and there is a large range of choice displayed. The inducements to enter one of the Services should prevail more than they have done of recent years An account is given of the conditions under which commissions can be obtained in the Navy, Army, Indian, and Air Force Medical Services, and in the Colonial and other Medical Services

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE powers and duties of the General Medical Council, or " General Council of Medical Education and Registration of the United Kingdom " to give the Council its full title, have been set out in detail in many previous Students' Numbers of THE LANCET. It is first a registering body: no person, even though his qualifications have been obtained by examination, is a legally qualified medical practitioner until his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that medical education reaches an efficient standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner convicted of felony or misdemeanour or adjudged guilty of conduct "infamous in a professional respect" Fourthly, to the Council is committed the codification of pharmaceutical remedies The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities

The Council at present consists of 38 members, of whom, as will be seen by the annexed list, all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives There are also three additional members appointed by the Privy Council under the Dentists Act, 1921, under which the powers and duties of the General Medical Council with regard to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the Dental Board of the United Kingdom (see p 479)

The President of the General Council is Sir Donald MacAlister, and the sitting members of the Council are enumerated in the Medical Register

THE EDUCATIONAL CURRICULUM

Professional Education.—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

The following are the General Medical Council's Regulations in regard to the registration of medical students which came into force on Jan 1st, 1923

Registration of Medical Students

1. Subject to such exceptions as the Council may from time to time allow, every medical student, at the commencement of his studies, should be registered under the conditions hereinafter set forth.

2. Before registration every candidate should produce evidence that he has attained the age of 17 years.

3 The minimum standard of General Education required is that of University matriculation or entrance examination in the Faculties of Arts or Pure Science.

4 Before registration as a student every applicant should be required to have passed an approved examination in general education, and, in addition thereto, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies.

5. A student who has diligently attended an approved course of instruction in elementary biology at a secondary school or other teaching institution recognised by a licensing body may be admitted to the professional examination in elementary biology immediately after his registration as a student.

6. The commencement of the course of professional study recognised by any of the licensing bodies should not be reckoned as dating earlier than 15 days before the date of registration.

7. Every person desirous of being registered as a medical student should apply to the registrar of the division of the United Kingdom in which he is residing, according to a prescribed form, copies of which may be had on application to the several licensing bodies, medical schools, and hospitals, or at the offices of the Medical Council; and should produce or forward to the registrar evidence that he has attained the age of 17 years, that he has passed a preliminary examination in general education recognised by the General Medical Council, and, in addition, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies, and that he has commenced medical study.

Regulations which the Council has prescribed for the maintenance of the register of medical students:—

1. It shall be delegated to the Education Committee to prepare and issue from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are specially recognised by, the General Medical Council.

2 The Council has recognised the undernoted university examinations, subject to the conditions specified below: viz, at Oxford University, Responsions; at Cambridge University, the Previous Examination; at the Scottish Universities, the Preliminary Examination; and the Matriculation Examination at the Universities of Birmingham,

MEDICAL ENGLISH

EVERY year the English and American vocabulary is enlarged by the addition of many new words Those conceived in popular nuptials and brought to birth as slang are plunged at once into the stream of everyday speech, the strongest win through, and if they live they live because they convey ideas not hitherto expressible so exactly—their utility, as much as their terseness saves them, but they perish (*T.D L*) when laziness and vacuity employ them in and out of season. But unfortunately not every new word has to go through the tests to which slang is subjected. The offspring of scientific brains are usually nursed from childhood in the enervating atmosphere of the printed page; their first plunge into public life is made in the Turkish bath of a learned society, but, no whit discouraged by the weedy growth of these semi-classical terms, their parents are urged by the fervour of procreation to subsequent efforts

Now any word has merit if it is short, easy to say, and really needed. On the other hand, brevity is not everything, and there is a real advantage in calling diseases or operations by names of Greek or Latin derivation because such names are descriptive, and their messages can be read by anyone of any nation having the necessary familiarity with a smattering of these dead languages But such descriptive words must be exact If they are carelessly put together, or "telescoped," or misspelt, they become unintelligible to scholar and Philistine alike, and a source of pain to both. Ornate and useless articles of clothing are going out of fashion, ornate architecture is not as popular as it has been; is it too much to hope that scientific language can be cleansed of its circumlocutions and made into a simpler medium for expressing facts? This can only be done if individuals apply to their sentences the same tests of relevance as they apply to signs and symptoms and laboratory phenomena, it can only be done if the full meaning of words is understood, and it can only be done, therefore, by the free use of medical dictionaries Fortunately these can easily be got and presumably they are more and more employed, for we note with pleasure that the one written by Dr T L Stedman has now reached its eighth edition [1] It was compiled by him in the leisure hours of a busy life as practitioner and editor, and it is a useful guide to the writing and reading of English Dr Stedman deplores the fact that "only a small percentage of even well-educated physicians of the present day can read the Greek characters," and registers his conviction that the elimination of Greek in schools has done much to barbarise the language of medicine and to make special medical dictionaries necessary He has yielded so far as to give the Greek words in Roman letters—a practice which it is hard to approve, since Greek words, however spelt, are not likely to convey much to those who know no Greek, whilst their familiar look is lost to those who might otherwise remember them. The general use of "c" instead of "k" to represent the Greek kappa—as in leucæmia (leukæmia)—can certainly be justified in itself, but there seems to be no reason for going on to pronounce the word as though the "c" were an "s," as Dr Stedman recommends This needlessly takes the word further away from its origin, as also—some would say—does the abolition of diphthongs which he approves because it is a simplication in accord with the Italian and Spanish derivatives of Latin He would have us write "hemorrhage" and "edematous," just as we write "equal" and "economy", but it is possible to reply that all four are regrettable if they lead to the original meanings and affinities being forgotten These, however, are little more than questions of taste, what is really important is that in Dr Stedman's dictionary we have a book which tells the reader and the writer the meaning of words and which commends the truer and purer forms The more general use of such books would go far to promote the writing of good scientific English

"A HASTY GENERALISATION"

To the Editor of THE LANCET

SIR,—I read the note in THE LANCET this week with the above title with much interest I think when the National Insurance Acts turned the medical practitioner into a Government official much was done to destroy the human touch which used to mark the relations between the doctor and his poorer patients In the war nurses and doctors saw death on such a large scale they became hardened, and after the war unfortunate elements blended, and produced a spirit which is, alas, not confined to any one profession. On all sides we see selfishness, a love of pleasure, a love of money, a lack of the spirit of self-sacrifice, which cause a feeling of resentment in many who remember better days The old-fashioned doctor and nurse may have lacked something in skill, but that lack was more than supplemented by a sympathetic interest in the patient—a human element too often lacking to-day.

There is a further adverse element at work—i e, a decline in religious belief, not without reason were the religious and medical professions closely related in the past, but they are largely divorced to-day I am inclined to think that the "hasty generalisation" is often a possibly unconscious revolt against this divorce It is not the duty of the doctor to preach, but when psycho-analysis shows the trouble to be mental rather than physical, the old-fashioned doctor with his hearty, "Trust in God, madame, He knows best," brushed away many a shadow, which the rather hopeless, "hard luck," or the superstitious "touch wood" of the irreligious modernist does little to relieve

As I go here and there I find a deep yearning for a word of sympathy, for the modern rush has eliminated the time required for the courtesies of life And we are the poorer for this In the United States for many years there has been a selfish materialism united with a worship of the Almighty Dollar, but only lately has this evil spirit invaded England. Our sick appreciate a word of comfort from doctor or nurse, and resent the loss of it; but I fear under modern conditions they must resign themselves to that loss

The National Insurance Acts, the war, and the lack of religion have smashed sympathy and real self sacrifice—for the present at least—I am, Sir, yours faithfully,

LOOKER ON

August 16th, 1926

A REGISTERED NURSES' BUREAU

A SCHEME has been organised to promote the interests of private nurses upon a plan which is already in existence in the United States Under the scheme the nurse pays a subscription of 3 guineas a year and a nominal registration fee of 2*s* 6*d*; only State registered nurses are eligible, and they will be registered on a general or a supplementary list, the latter implying allocation only to some particular branch of nursing. The subscription does not run until employment is found for the nurse, the registration fee securing a place on the waiting-list In order to be on the register a nurse must fill in an application form, enclosing her State certificate and proofs of training, while she is invited to give a very detailed personal account of herself in other ways. The Bureau is a limited liability company with an honorary advisory committee of well-known medical men, the registrars are fully-trained and registered nurses Any nurse wishing to obtain an application form should write to Mr Alfred Rose, the managing director of the Bureau, at 55, Chancery-lane, London, W C

TRAVEL IN FRANCE

THE Directors of the Office Français du Tourisme (56, Haymarket, London, S W. 1) write to say that, contrary to current rumour, no new or special taxes have been as yet levied on foreign visitors to France Existing taxes have, however, been increased to some extent The cost of the Identity Card has been raised from 68 to 375 francs, but as this card need only be obtained after a two months' stay it does not affect the tourist The cost of the Laisser Passer for motor-cars has been increased from 2 50 to 10 francs per day The increase of 30 per cent in the price of passenger tickets which came into force on August 16th will not make much difference in the total fare for continental travellers from Great Britain.

OVER-SIZE BABIES

To the Editor of THE LANCET

SIR,—One of my patients, a woman of 35, has had three children weighing respectively 10, 10¼, and 11¾ lb She is rather undersized and slender and her husband is also undersize and weighs less than 10 st I have looked up many authorities and can find no reference to the prevention of a repetition of these, which naturally she dreads She is very active and is a small eater Perhaps you or some of your readers could help me Probably it is a matter of diet

I am, Sir, yours faithfully,

P J B

August 16th, 1926

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 7TH 1926

Notifications—The following cases of infectious disease were notified during the week—Small-pox, 60 (last week 60), scarlet fever, 1045, diphtheria, 756, enteric fever, 36, pneumonia, 318, puerperal fever, 35, cerebro-spinal fever, 5, acute poliomyelitis, 20, acute polio-encephalitis, 4, encephalitis lethargica, 34, continued fever, 1, dysentery, 7, ophthalmia neonatorum, 99 There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths—In the aggregate of great towns, including London, there were no deaths from small-pox, 5 (0) from enteric fever, 13 (3) from measles 2 (0) from scarlet fever, 16 (1) from whooping-cough, 26 (7) from diphtheria 98 (15) from diarrhœa and enteritis under 2 years of age and 10 (2) from influenza The returns for diarrhœa and enteritis show a small drop from those of the previous week. The figures in parentheses are those for London itself

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

A Guide to the Facilities for Obtaining the Various Medical Degrees and Other Qualifications for the British Medical Register

I —ENGLAND AND WALES

THE UNIVERSITIES

UNIVERSITY OF OXFORD

This University confers two degrees in Medicine, those of *B.M.* and *D.M*, two in Surgery, *B Ch* and *M Ch*, and diplomas in *Public Health and Ophthalmology*

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees The most convenient course for the B A degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. To obtain the degrees of B M and B Ch the following examinations must be passed. 1. Preliminary subjects: Physics and Chemistry, Zoology, and Botany 2 Professional (*a*) First Examination Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Honour School of Natural Science, Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Honour School of Natural Science; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The first B M examination may be passed at any time after the Preliminary Scientific examinations Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately

At any time after passing the First Examination, the candidate can, on producing certificates, present himself for examination in the subjects of Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology, but cannot, unless he is already a registered medical practitioner, enter for examination in Medicine, Surgery and Midwifery until the eighteenth term from his matriculation, nor until a period of at least thirty-three months has elapsed from the date of passing the First B M Examination. He must pass in Medicine, Surgery and Midwifery at one and the same time

Before admission to the Second B M Examination, the student must produce certificates of having attended laboratory courses in Pathology, Bacteriology and Pharmacology either in Oxford or in a recognised medical school He must also produce certificates of having acted as Clinical Clerk and Dresser, each for six months, in a medical school-approved by the University, of post-mortem clerking, of attendance on Labours, of instruction in Infectious Diseases and Ophthalmology, of proficiency in vaccination and the administration of anæsthetics, and of three academic years of Hospital Practice.

The degree of B Ch is granted with that of B M after passing the above examinations The degree of D M. is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by the examiners for the B M degree whose subjects are dealt with therein and by Professors in the Faculty of Medicine The degree of M Ch is granted after examination to Bachelors of Surgery in the University who have entered upon their twenty-first term, and who are Members of the Surgical Staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for a period of six months The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B M examination

The examinations for the Diploma in Public Health (see p 474) in two parts are held in Trinity and Michaelmas terms (until further notice in Trinity term only), that for the Diploma in Ophthalmology (see p 474) is held annually in July

Travelling Fellowship, Scholarships, and Prizes—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300 The examination is in Physiology, Pathology, and Hygiene, and is partly "practical" Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University They may offer any one of the subjects, Animal Physiology, Botany, Zoology A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year on the nomination of the Regius Professor of Medicine The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years, the exhibitions vary in value from £30 to £90 per annum The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

In addition to the University Lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the B.A. degree

In the Radcliffe Infirmary and County Hospital elementary clinical instruction is given by the Regius Professor of Medicine, the Litchfield Lecturers in Medicine and Surgery, and the other physicians and surgeons Instruction is also given in post-mortem work and Clinical Pathology in connexion with the courses in Pathology Post-graduate courses are held at the beginning of October

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1923 (both of which are published by the Clarendon Press); from the Regius Professor of Medicine, from the Professors in the several departments of medical science; and from the Dean of the School of Medicine, Department of Medicine, Museum, Oxford

University of Oxford Radcliffe Infirmary and County Hospital.—*Courses of instruction* are given in connexion with the Oxford University Medical School These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation (4) Pathological demon-

Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, and Wales

3. The conditions prescribed by the Council are :—(1) The standard of the examination shall not be lower than that of the University Matriculation Examinations in the Faculties of Arts and Pure Science. (2) The certificate shall bear evidence that the candidate has passed in the following subjects, viz. :—(*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English (*d*) An additional subject or subjects, as required by the regulations of the particular examination, to be chosen from the subjoined list, viz. · History, Geography, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose.

4 Subject to the conditions specified above (Section 3, Subsection (2)), the Council will recognise all examinations conducted by recognised authorities in Great Britain accepted by one or more of the above-named Universities as equivalent for purposes of Matriculation to an examination named in the preceding list (Section 2). *Bristol University* · Higher School Certificate Examination ; Schools Certificate Examination. *Cambridge Local Examinations and Lectures Syndicate* · Higher School Certificate Examination ; School Certificate Examination *Central Welsh Examination Board* · Senior Certificate Examination. *Durham University:* Higher Certificate Examination ; School Certificate Examination *London University:* General School Examination, Higher School Certificate Examination. *Northern Universities Joint Matriculation Board* Higher Certificate Examination, School Certificate Examination *Oxford and Cambridge Schools Examination Board:* Higher Certificate Examination ; School Certificate Examination. *Oxford Delegacy for Local Examinations.* Higher School Certificate Examination ; School Certificate Examination. *Scottish Education Department:* Leaving Certificate Examination.

5. The Council will continue to recognise examinations conducted by educational bodies other than those (referred to in Section 4) directly recognised by the Universities of Great Britain Recognition will not be extended under this section to any examination unless the Council is satisfied (1) that in scope and standard it is equivalent to a recognised Matriculation Examination of a British University, and (2) that it fulfils the conditions specified by the Council (Section 3, Sub-section (2)) Such examinations are ·—The College of Preceptors (England) Senior Certificate. The Educational Institute of Scotland : Preliminary Medical Certificate.

Examinations in Ireland—6 Subject to the specified conditions (Section 3, Sub-section (2)), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, the Matriculation Examinations of the National University of Ireland and the Queen's University of Belfast, the Preliminary Examination of the Irish Royal Colleges of Physicians and Surgeons, the Leaving Certificate of the Intermediate Education Board of the Irish Free State, and the Senior Leaving Certificate of the Ministry of Education of Northern Ireland, and all examinations accepted by one or more of the Universities as equivalent for purposes of entrance or Matriculation, to the above-named examinations.

7. The Council will recognise the Final Examinations for Degrees in Arts and Science of any University of the United Kingdom or of the British Dominions

Colonial Examinations,—8. Subject to the specified conditions (Section 3, Sub-section (2)), the Council will recognise all examinations of Colonial Universities which are accepted by one or more of the British Universities as equivalent, for purposes of Matriculation, to an examination named in the list of examinations recognised by the Council (Section 2)

A copy of the Medical Students Register prepared by each of the Branch Registrars is transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who supplies an alphabetical list of all students registered in the preceding year to each of the licensing bodies in the United Kingdom, and to each of the several medical schools and hospitals

All applications for special exceptions to the foregoing regulations as to registration should be addressed to the Registrar of the General Council

Lists of Universities (including their Colleges and Medical Schools) and Schools of Medicine at which Medical Study may be Commenced in the United Kingdom—1. Universities (including their colleges) Aberdeen University, Belfast, Queen's University, Birmingham University, Bristol University, Cambridge University; Dublin University (including Trinity College), Durham University (including the Durham College of Medicine), Edinburgh University; Glasgow University (including Queen Margaret College), Ireland, National University (including University College, Cork, University College, Dublin; University College, Galway), Leeds University; Liverpool University, London University (including the following Schools and Colleges St Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College, King's College Hospital, London Hospital, St Mary's Hospital, Middlesex Hospital, St Thomas's Hospital, University College, Westminster Hospital, London (Royal Free Hospital) School of Medicine for Women, Bedford College, Royal Holloway College; Manchester, Victoria University, Oxford University; St Andrews University (including University College, Dundee), Sheffield University; Wales, University of (including University College of Wales, Aberystwyth, University College of North Wales, Bangor, University College of South Wales and Monmouthshire, Cardiff, Welsh National School of Medicine, Cardiff, University College, Swansea). 2 Schools of Medicine Recognised by the Licensing Bodies —*Dublin. Royal College of Surgeons, Schools of Surgery; Edinburgh* · School of Medicine of the Royal Colleges; Glasgow · Anderson's College, St Mungo's College

The address of the Registrar, to whom further communications should be addressed, is as follows · The Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1.

Medical Registration and the Irish Free State.

In August, 1925, the announcement was made by the Government of the Irish Free State that the Executive Council had decided not to seek the continuation of the United Kingdom arrangement whereby the medical profession in Ireland is controlled by the General Medical Council. This decision was unexpected, as it had been understood that the Irish Government was content to continue the existing system of registration It caused much perturbation as it was feared that any alteration, by placing an obstacle in the way of Irish medical men seeking admission to the General Register, might influence the Irish medical schools to their hurt During the 12 months that have passed since that pronouncement conferences have taken place between representatives of the profession and members of the Government Although no official pronouncement has yet been made on the subject, it is believed that a scheme has been devised which will protect the right at present enjoyed by medical men qualified in Ireland of registering in the General Register, and at the same time will secure to the Irish Free State the control of those who desire to practise in that country As no publication of the proposed scheme has taken place, it is not possible to indicate the particulars of it with precision Students of medicine in the Irish Free State, and those who intend to enter on the study of medicine, may, however, have a fair security that their choice of a place of practice will not be limited by any future change

For the present, by temporary legislation in the Irish Parliament, the powers of the General Council are exercised as heretofore in the Irish Free State at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby, or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine, the Lister Institute of Preventive Medicine, the Maudsley and Bethlem Royal Hospitals are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*) and the degree of B.D.S. (*Bachelor of Dental Surgery*): the two higher degrees being open only to candidates holding the M.B., B.S. degrees of the University.

The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W. 7.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) *Attended* prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics including Mechanics and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.). Organic Chemistry.—This examination will take place twice in each year, commencing on the Tuesday following the third Monday in March and on the second Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine, (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine, (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital, (14) The conduct of at least 20 Labours; (15) Antenatal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work, (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine, (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year and commences on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology and Rhinology. A thesis may be submitted as for M.D.

Bachelor of Pharmacy.—The Senate has approved the institution of the Degree of Bachelor of Pharmacy (B.Pharm.). The course for this Degree extends over three years.

strations and instruction in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. The hospital contains 225 beds

UNIVERSITY OF CAMBRIDGE

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University He must pass the Previous Examination in Classics, Mathematics, &c., before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, and certain other certificates, or by being a graduate of certain other Universities in the United Kingdom He may then devote himself to medical study in the University, &c Or he may, as nearly all students now do, proceed to take a degree in Arts by passing the Examinations for the ordinary B A degree, or an Honours degree by passing a Tripos Examination The Natural Sciences Tripos is taken most frequently by medical students, as some of the subjects are practically the same as those for the first and second M B

For the degree of *Bachelor of Medicine* (*M B*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I of the Natural Sciences Tripos and the first and second examinations for M B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for M.B The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research

There are three examinations for M B. The *first* includes (1) General and Inorganic Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology These parts may be taken together or separately. The *second* is divided into three parts—viz., (1) Organic Chemistry, (2) Human Anatomy and Physiology; and (3) Pharmacology and General Pathology The *third* is divided into two parts (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women), and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology) The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic Candidates who have passed both parts of the third M B. examination are admitted to the registrable degree of *Bachelor of Surgery* (*B Chir*) without separate examination and without keeping an Act

The degree of *Doctor of Medicine* (*M D.*) may be taken three years after that of M.B. or four years after that of M A The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A, to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine

For the degree of *Master of Surgery* (*M.Chir*) the candidate must have passed all the examinations for B Chir., or, if he is an M A, have obtained some other registrable qualification in surgery. He is required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Chir

Diplomas are granted in Public Health, in Hygiene, in Tropical Medicine and Hygiene, in Medical Radiology and Electrology, and in Psychological Medicine Candidates must hold a recognised medical qualification (See p 473)

Women Students—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the M B Examinations

University Prize in Medicine—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, The Registry, Cambridge

Addenbrooke's Hospital.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year, and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Dr Aldren Wright.

UNIVERSITY OF LONDON

The University of London was established by Royal Charter in 1836 as an examining and degree-conferring body with affiliated colleges but no direct teaching functions In 1900 it was reconstituted under the Act of Parliament, 1898, and became a teaching as well as an examining body Many schools already existing became constituent colleges, including all the metropolitan medical schools Lecturers were also appointed in special subjects

Teaching Staff.—The teaching staff of the University is organised under two heads · 1 Appointed teachers—i e, such as are appointed by the University 2. Recognised teachers—i e, those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective schools

Internal and External Students—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School Students receive their training in Preventive Medicine, Pathology, Bacteriology, and Biochemistry here, and are encouraged to undertake Research Special facilities are available for Post-graduate Research and Study

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital adjoining Special demonstrations are arranged for Post-graduates

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, "The Cuthbert Lockyer Collection"

Students' Club —The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society An athletic ground, comprising six acres, has recently been acquired and is now in use

Women Students —Women students are admitted to the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments

Fees —Entrance Primary and Intermediate, 10 guineas, Final, 8 guineas, Annual, £42

Further information may be obtained on application to the Dean, Dr. W. J Fenton, Medical School, Charing Cross Hospital, London, W C

ST GEORGE'S HOSPITAL —This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds Children's beds are placed in the women's wards Two wards are allotted to ophthalmic cases

Entrance Scholarships and Endowed Prizes of a total value of £700 are awarded annually; a detailed list is placed below The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St George's to carry out the necessary courses of instruction at that College Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office —Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each, Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum, Medical Registrarship at £200 per annum, Surgical Registrarship at £200, Assistant Curatorship of the Museum at £100, Obstetric Assistantship (Resident) at £50, the post of Resident Anæsthetist at £100, the posts (2) of Junior Anæsthetists, each at £30 The St George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs Students have the advantage of a library of medical and scientific books which is kept up to date

Scholarships and Prizes —At this school five entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively, (*c*) and (*d*) two University Entrance Scholarships, 90 guineas and £70 respectively; (*e*) Devitt-Pendlebury Scholarship, £50, Anatomy and Physiology, except in the case of (*c*), subject of examination for which is General Pathology

This year, in addition to these Scholarships, Exhibitions, each of the value of £40 and up to six in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination The others are as follows. (*f*) Allingham Scholarship in Surgery for Students qualified not more than two years, £85, (*g*) and (*h*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing, (*i*) H C Johnson Memorial Prize, £19, Practical Anatomy, (*j*) Pollock Prize, £23, Physiology, Physiological Chemistry, and Histology, (*k*) Clarke Prize, £5, (*l*) Thompson Medal, £9, Clinical Reports; (*m*) Brodie Prize, £8, Clinical Reports, (*n*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*o*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications

Further information may be obtained from the Dean of the Medical School, Dr. A Feiling

---

GUY'S HOSPITAL —This hospital, founded by Thomas Guy in 1724 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 616 beds The whole of the medical school has been rebuilt during the last 27 years It provides ample accommodation, with modern equipment, for all the non-clinical subjects of the medical curriculum Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology and genito-urinary diseases, house physician in the department for diseases of children, clinical assistants, clerks to anæsthetists, surgeons' dressers, clerks to medical units, post-mortem clerks, extern obstetric dressers, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

The following special departments are attached to the hospital Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anæsthetics dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children)

Scholarships —Six entrance scholarships are awarded annually as follows —(*a*) one War Memorial scholarship, providing a free Medical Education for five years of the value of £200, to be awarded alternately in Arts and Science (next award, July, 1928), (*b*) one Open Arts Scholarship of £100 for students under 21 years of age, Latin, English, Greek, or French or German, Arithmetic, Euclid, and Algebra; (*c*) one Open Junior Science scholarship for students under 21 years, £100, subjects, any two of the following *Inorganic Chemistry*, Physics, and Biology; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in July, to candidates who have attended the Preliminary Science Classes at this School, (*e*) two open Science scholarships (1) a War Memorial scholarship of the value of £80, awarded annually in September, (2) an open scholarship of the value of £80, awarded annually in September, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School; subjects, any two of the following: *Anatomy*, *Physiology*, Organic Chemistry, Pharmacology, General Pathology.

Fees.—Matriculation £2 12*s* 6*d* for each entry, at provincial examinations an additional local fee is charged. First examination for Medical Degrees: £6 6*s*. for each entry to the entire examination. For re-examination in one subject the fee is £2 2*s*. Second examination, Part I: £3 3*s*., repeated on each subsequent entry, Part II. £9 9*s* for the whole examination. Third examination: £12 12*s* for each entry to the whole examination. M.D. Examination: £21; for re-examination £10 10*s*. M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON[1]

St Bartholomew's Hospital and College.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley. It receives over 9000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day, except Saturdays, at 1.30 P.M., and Surgical consultations are held on Thursdays at the same hour. Medical consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical lectures on all special subjects are also given. Wholetime Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board, and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the Medical College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry. *The Medical School Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. Facilities for research work are afforded in the Clinical Units and Laboratories of pathological and other departments. *A Vacation Post-graduate Course*, adapted to the needs of general practitioners, is given annually. The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Scholarships given in aid of Medical Study.—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100, (*c*) Entrance Scholarship in Arts, £100, (*d*) Jeaffreson Exhibition, £50, and (*e*) Shuter Scholarship, £50—a full or University course at St Bartholomew's Hospital is required. The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, Anatomy, and Pathology. (*c*) and (*d*) are awarded after examination in Mathematics, Latin or Greek or French or German, a second language or Chemistry or Physics; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The more important of the other Scholarships and prizes are as follows:—Four Junior Scholarships—(*f*) No. 1, £30, Anatomy and Physiology, (*g*) No. 2, £20, Anatomy and Physiology, (*h*) No. 3, £25, Chemistry, Physics, and Biology, (*i*) No. 4, £15, Chemistry, Physics, and Biology. (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine, (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery, (*n*) Sir G. Burrows Prize, 10 guineas, Pathology, (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy, (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105, (*r*) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115, and (*s*) Baly Scholarship in Clinical Medicine, £75, awarded by examination.

Information may be obtained on application to the Dean of the Medical College, Dr. T. W. Shore. The Warden of the Residential College is Mr. R. M. Vick.

Charing Cross Hospital.—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Treatment.

Appointments.—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year.

Primary and Intermediate Studies.—By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk.

Final Studies.—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica and Operative Surgery.

---

[1] For Ancillary Metropolitan Medical Schools see p. 436.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School Students receive their training in Preventive Medicine, Pathology, Bacteriology, and Biochemistry here, and are encouraged to undertake Research Special facilities are available for Post-graduate Research and Study

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital adjoining Special demonstrations are arranged for Post-graduates

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, " The Cuthbert Lockyer Collection "

Students' Club—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society An athletic ground, comprising six acres, has recently been acquired and is now in use

Women Students—Women students are admitted to the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments

Fees—Entrance Primary and Intermediate, 10 guineas; Final, 8 guineas, Annual, £42

Further information may be obtained on application to the Dean, Dr W J Fenton, Medical School, Charing Cross Hospital, London, W C

ST GEORGE'S HOSPITAL—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds Children's beds are placed in the women's wards Two wards are allotted to ophthalmic cases

Entrance Scholarships and Endowed Prizes of a total value of £700 are awarded annually, a detailed list is placed below The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St George's to carry out the necessary courses of instruction at that College Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum, Medical Registrarship at £200 per annum, Surgical Registrarship at £200, Assistant Curatorship of the Museum at £100, Obstetric Assistantship (Resident) at £50, the post of Resident Anæsthetist at £100, the posts (2) of Junior Anæsthetists, each at £30 The St George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs Students have the advantage of a library of medical and scientific books which is kept up to date

Scholarships and Prizes—At this school five entrance scholarships are given, the money value and the subjects of examination being as follows · (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively, (c) and (*d*) two University Entrance Scholarships, 90 guineas and £70 respectively, (*e*) Devitt-Pendlebury Scholarship, £50, Anatomy and Physiology, except in the case of (*c*), subject of examination for which is General Pathology

This year, in addition to these Scholarships, Exhibitions each of the value of £40 and up to six in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination The others are as follows (*f*) Allingham Scholarship in Surgery for Students qualified not more than two years, £85, (*g*) and (*h*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing, (*i*) H C Johnson Memorial Prize, £19, Practical Anatomy, (*j*) Pollock Prize, £23, Physiology, Physiological Chemistry, and Histology, (*k*) Clarke Prize, £5, (*l*) Thompson Medal, £9, Clinical Reports; (*m*) Brodie Prize, £8, Clinical Reports; (*n*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*o*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications

Further information may be obtained from the Dean of the Medical School, Dr. A Feiling

---

GUY'S HOSPITAL—This hospital, founded by Thomas Guy in 1724 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 616 beds The whole of the medical school has been rebuilt during the last 27 years It provides ample accommodation, with modern equipment, for all the non-clinical subjects of the medical curriculum Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology and genito-urinary diseases, house physician in the department for diseases of children, clinical assistants, clerks to anæsthetists, surgeons' dressers, clerks to medical units, post-mortem clerks, extern obstetric dressers, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

The following special departments are attached to the hospital Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actino-therapeutics, anæsthetics dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children)

Scholarships—Six entrance scholarships are awarded annually as follows—(*a*) one War Memorial scholarship, providing a free Medical Education for five years of the value of £200, to be awarded alternately in Arts and Science (*next award, July, 1928*), (*b*) one Open Arts Scholarship of £100 for students under 21 years of age, Latin, English, Greek, or French or German, Arithmetic, Euclid, and Algebra, (*c*) one Open Junior Science scholarship for students under 21 years, £100, subjects, any two of the following Inorganic Chemistry, Physics, and Biology; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in July, to candidates who have attended the Preliminary Science Classes at this School, (*e*) two open Science scholarships (1) a War Memorial scholarship of the value of £80, awarded annually in September, (2) an open scholarship of the value of £80, awarded annually in September, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School, subjects, any two of the following Anatomy, Physiology, Organic Chemistry, Pharmacology, General Pathology.

Fees —Matriculation £2 12*s* 6*d* for each entry, at provincial examinations an additional local fee is charged First examination for Medical Degrees £6 6*s* for each entry to the entire examination For re-examination in one subject the fee is £2 2*s* Second examination, Part I £3 3*s*, repeated on each subsequent entry, Part II £9 9*s* for the whole examination Third examination · £12 12*s* for each entry to the whole examination M D Examination · £21, for re-examination £10 10*s* M S Examination: As for M D

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Academic Registrar, University of London, South Kensington, S W 7

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON[1]

St Bartholomew's Hospital and College —The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley It receives over 9000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work Surgical operations take place every day, except Saturdays, at 1 30 P M, and Surgical consultations are held on Thursdays at the same hour Medical consultations are held on Thursdays at 3 15 P M The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions Clinical lectures on all special subjects are also given Wholetime Clinical Units under Professors of Medicine and Surgery have been established

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board, and receive a salary of £80 a year Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students A residential college is attached to the hospital

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre There is a chemical laboratory attached to the Medical College as well as a laboratory devoted to instruction in Public Health A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry *The Medical School Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy The pathological museum is the most complete in the kingdom A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology

Special Classes for the Primary and Final F R C S are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year Facilities for research work are afforded in the Clinical Units and Laboratories of pathological and other departments *A Vacation Post-graduate Course*, adapted to the needs of general practitioners, is given annually The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range

Scholarships given in aid of Medical Study —At the school various Scholarships, prizes, &c, are given For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100, (*c*) Entrance Scholarship in Arts, £100, (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St Bartholomew's Hospital is required The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology Anatomy, and Pathology, (*c*) and (*d*) are awarded after examination in Mathematics, Latin or Greek or French or German, a second language or Chemistry or Physics, (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology The more important of the other Scholarships and prizes are as follows —Four Junior Scholarships—(*f*) No 1, £30, Anatomy and Physiology, (*g*) No 2, £20, Anatomy and Physiology, (*h*) No 3, £25, Chemistry, Physics, and Biology, (*i*) No 4 £15 Chemistry, Physics, and Biology. (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry. (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine, (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (*n*) Sir G Burrows Prize, 10 guineas, Pathology, (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy, (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology, (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105, (*r*) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115, and (*s*) Baly Scholarship in Clinical Medicine, £75, awarded by examination

Information may be obtained on application to the Dean of the Medical College Dr T W Shore The Warden of the Residential College is Mr R M Vick

Charing Cross Hospital —The Hospital, to which the School is attached, contains 300 beds Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Treatment

Appointments —In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year

Primary and Intermediate Studies —By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk

Final Studies —These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations Departments are also available for other final subjects of Materia Medica and Operative Surgery

---

[1] For Ancillary Metropolitan Medical Schools see p 436

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School Students receive their training in Preventive Medicine, Pathology, Bacteriology, and Biochemistry here, and are encouraged to undertake Research Special facilities are available for Post-graduate Research and Study

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital adjoining Special demonstrations are arranged for Post-graduates.

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, "The Cuthbert Lockyer Collection"

Students' Club—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society An athletic ground, comprising six acres, has recently been acquired and is now in use.

Women Students—Women students are admitted to the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments

Fees—Entrance · Primary and Intermediate, 10 guineas; Final, 8 guineas; Annual, £42

Further information may be obtained on application to the Dean, Dr W J Fenton, Medical School, Charing Cross Hospital, London, W C

ST GEORGE'S HOSPITAL—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds Children's beds are placed in the women's wards Two wards are allotted to ophthalmic cases

Entrance Scholarships and Endowed Prizes of a total value of £700 are awarded annually, a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St George's to carry out the necessary courses of instruction at that College Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office.—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum; Medical Registrarship at £200 per annum, Surgical Registrarship at £200, Assistant Curatorship of the Museum at £100, Obstetric Assistantship (Resident) at £50, the post of Resident Anæsthetist at £100. the posts (2) of Junior Anæsthetists, each at £30 The St George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs Students have the advantage of a library of medical and scientific books which is kept up to date

Scholarships and Prizes—At this school five entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively, (*c*) and (*d*) two University Entrance Scholarships, 90 guineas and £70 respectively; (*e*) Devitt-Pendlebury Scholarship, £50, Anatomy and Physiology, except in the case of (*c*), subject of examination for which is General Pathology

This year, in addition to these Scholarships, Exhibitions each of the value of £40 and up to six in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*f*) Allingham Scholarship in Surgery for Students qualified not more than two years, £85, (*g*) and (*h*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing, (*i*) H. C Johnson Memorial Prize, £19, Practical Anatomy; (*j*) Pollock Prize, £23, Physiology, Physiological Chemistry, and Histology; (*k*) Clarke Prize, £5; (*l*) Thompson Medal, £9, Clinical Reports; (*m*) Brodie Prize, £8, Clinical Reports; (*n*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*o*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications

Further information may be obtained from the Dean of the Medical School, Dr. A. Feiling

GUY'S HOSPITAL—This hospital, founded by Thomas Guy in 1724 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 616 beds The whole of the medical school has been rebuilt during the last 27 years. It provides ample accommodation, with modern equipment, for all the non-clinical subjects of the medical curriculum Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology and genito-urinary diseases, house physician in the department for diseases of children, clinical assistants, clerks to anæsthetists, surgeons' dressers, clerks to medical units, post-mortem clerks, extern obstetric dressers, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

The following special departments are attached to the hospital Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system dermatology, otology, actinotherapeutics, anæsthetics dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children)

Scholarships.—Six entrance scholarships are awarded annually as follows.—(*a*) one War Memorial scholarship, providing a free Medical Education for five years of the value of £200, to be awarded alternately in Arts and Science (next award, July, 1928); (*b*) one Open Arts Scholarship of £100 for students under 21 years of age, Latin, English, Greek, or French or German, Arithmetic. Euclid, and Algebra; (*c*) one Open Junior Science scholarship for students under 21 years, £100; subjects, any two of the following: Inorganic Chemistry, Physics, and Biology; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in July, to candidates who have attended the Preliminary Science Classes at this School; (*e*) two open Science scholarships. (1) a War Memorial scholarship of the value of £80, awarded annually in September, (2) an open scholarship of the value of £80, awarded annually in September, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School; subjects, any two of the following: Anatomy, Physiology, Organic Chemistry, Pharmacology, General Pathology.

Fees —Matriculation £2 12*s* 6*d* for each entry, at provincial examinations an additional local fee is charged. First examination for Medical Degrees £6 6*s* for each entry to the entire examination For re-examination in one subject the fee is £2 2*s* Second examination, Part I £3 3*s*, repeated on each subsequent entry ; Part II £9 9*s* for the whole examination Third examination · £12 12*s* for each entry to the whole examination M D Examination. £21 ; for re-examination £10 10*s* M S Examination : As for M D

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Academic Registrar, University of London, South Kensington, S W 7

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON [1]

St Bartholomew's Hospital and College —The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley It receives over 9000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work Surgical operations take place every day, except Saturdays, at 1 30 P M, and Surgical consultations are held on Thursdays at the same hour Medical consultations are held on Thursdays at 3 15 P M The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions Clinical lectures on all special subjects are also given Wholetime Clinical Units under Professors of Medicine and Surgery have been established

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board, and receive a salary of £80 a year Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students A residential college is attached to the hospital.

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre There is a chemical laboratory attached to the Medical College as well as a laboratory devoted to instruction in Public Health A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry *The Medical School Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy The pathological museum is the most complete in the kingdom A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Special Classes for the Primary and Final F R C S are held twice yearly *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year Facilities for research work are afforded in the Clinical Units and Laboratories of pathological and other departments *A Vacation Post-graduate* Course adapted to the needs of general practitioners, is given annually The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range

Scholarships given in aid of Medical Study —At this school various Scholarships, prizes, &c, are given For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100, (*c*) Entrance Scholarship in Arts, £100, (*d*) Jeaffreson Exhibition, £50 ; and (*e*) Shuter Scholarship, £50—a full or University course at St Bartholomew's Hospital is required The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology Anatomy, and Pathology, (*c*) and (*d*) are awarded after examination in Mathematics, Latin or Greek or French or German, a second language or Chemistry or Physics, (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology The more important of the other Scholarships and prizes are as follows —Four Junior Scholarships—(*f*) No 1, £30, Anatomy and Physiology, (*g*) No 2, £20, Anatomy and Physiology, (*h*) No 3 £25, Chemistry, Physics, and Biology, (*i*) No 4, £15, Chemistry, Physics, and Biology. (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry. (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine, (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery, (*n*) Sir G Burrows Prize, 10 guineas, Pathology, (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy, (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105, (*r*) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115, and (*s*) Baly Scholarship in Clinical Medicine, £75, awarded by examination

Information may be obtained on application to the Dean of the Medical College Dr T W Shore The Warden of the Residential College is Mr. R M Vick

Charing Cross Hospital —The Hospital, to which the School is attached, contains 300 beds Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Treatment.

Appointments —In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year

Primary and Intermediate Studies —By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk

Final Studies —These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations Departments of Materia Medica and Operative Surgery are also available for other final subjects

---

[1] For Ancillary Metropolitan Medical Schools see p 436

To each medical and surgical firm throughout the hospital there is attached a First Assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations Special courses of lectures and demonstrations are arranged in Medicine and Surgery and their ancillary subjects Opportunities for research are provided under the supervision of the staff

Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital Holders of resident appointments have free board. Special classes are held for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, for the Membership of the Royal College of Physicians, and for other higher examinations Special entries for medical and surgical practice can be made A residential Hostel on hospital grounds is provided for the convenience of students The Union Athletic Ground, 13 acres, is within easy reach of the hospital

Scholarships and Prizes —The following is a list of the Scholarships and Prizes —Price Scholarship £100, and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London, Epsom College Scholarship, free education, subjects of First Medical Examination as above, Price Scholarship, open to students of Oxford and Cambridge Universities, £75, Human Anatomy and Physiology; Buxton Prize, £40, subjects of Anatomy and Physiology; three Prizes for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynæcology; Sutton Prize, £20, Pathology, Duckworth Nelson Prize, biennial, £10, Practical Medicine, and Surgery, Letheby Prizes (2), £25, Chemistry and Chemical Pathology, eight Dressers' Prizes, amounting to £40, zeal, efficiency, and knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £60, Clinical Surgery, Treves Prize, £15, Clinical Surgery, two Practical Anatomy Prizes, £6 and £4 respectively, Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology, James Anderson Prizes (4), £20, Elementary Clinical Medicine, Arnold Thompson Prize, £15, Diseases of Children, K E D Payne Prize, £20, Pathology, and Liddle Prize, triennial, £120

Medical Research Funds —Funds to the value of over £90 000 permit of financial assistance being given to students and graduates engaged in Medical Research

Dean Professor William Wright, London Hospital Medical College, E 1

ST MARY'S HOSPITAL MEDICAL SCHOOL —The Hospital and Medical School are situated close to Paddington station (G W R.) having on one side a poor district of 500 000 persons, and on the other side the residential districts of Kensington and Bayswater The hospital contains 288 beds and, by a scheme of affiliation, for teaching purposes, of certain neighbouring hospitals, the teaching facilities extend over 1000 beds The Athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains A large pavilion has recently been added

Clinical Facilities —Clinical Units in Medicine and Surgery were established in 1920, and have now been formally recognised by the University Grants Committee, St Mary's being one of the six Medical Schools in London which enjoy this privilege Lying-in beds have recently been added, and, in addition to this, arrangements have been made by which all students take out a short course of instruction in Practical Midwifery at Queen Charlotte's Hospital without additional fee

Institute of Pathology and Research —Students specially interested in Pathology and Bacteriology have singular advantages at St Mary's The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F R S

Appointments —Research Scholarships of £200 each are awarded annually to students working in the departments of the institute; and research beds have been instituted Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision Seventy-two of these posts are available annually Numerous appointments are open to newly-qualified members of the Medical School, including ten salaried posts with salaries varying from £200 to £750 per annum

Complete Curriculum —The Medical School provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts Terms begin in October, January, and April.

Entrance Scholarships —Two Entrance Scholarships of the value of £210 each are awarded annually, and one or more University Scholarships of £200.

Fees.—Composition Fee for entire curriculum (5½ years) £200 in one sum, or £210 by four annual instalments Composition Fee for Clinical curriculum (2½ years) 90 guineas in one sum, or 95 guineas by two annual instalments As an alternative, students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas

---

MIDDLESEX HOSPITAL —The hospital contains over 450 beds, with special wards for Cancer, Maternity and Gynæcological and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin, Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases There is also an Electro-Therapeutic department The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects In the Electro-Therapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment

The Medical School, which includes the Bland-Sutton Institute of Pathology and the Cancer Research Laboratories is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly, commencing in April and October. Ample laboratory and classroom accommodation is provided The teaching staff includes 6 Professors, 32 recognised Teachers, 10 Demonstrators, 4 tutors The Bland-Sutton Institute of Pathology is completely equipped for routine hospital investigations, teaching and research work, and contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility

Other features of interest are · the institution of a course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D P H course, under the direction of Dr Charles Porter, M O H, St Marylebone Primary F R C S class will resume in July

Special classes are held to prepare students for the Intermediate Examinations of the Universities

Hospital Appointments —All appointments are made without fee of any kind, and the following are appointed at intervals annually six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anæsthetist, and two resident officers to the special departments The medical and surgical casualty officers are appointed twice a year Nine registrars are appointed annually Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments Clinical clerks and surgical dressers are also appointed in every department

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates the term "military service" meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the war; or (2) in respect of other approved duties in connexion with national defence.

The Dean of the Medical School is Prof. T. B. Johnston, from whom information may be obtained.

University of London: King's College.—The Medical Faculty at this College deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants to students entering the College directly and also to students of the following four hospital schools which prepare only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital. The Faculty is open to both men and women.

Scholarships.—(*a*) Two Warneford Entrance Scholarships of £30 each for four years. Examination in April, subjects selected from Divinity, Classics, Science. (*b*) Sambrooke Scholarship of £30 for three years. Examination in April, subjects selected from Classics, Science. (*c*) Worsley Scholarships £100 in five annual instalments of £20. (*d*) Rabbeth Scholarships of £30 and £15 for best work in first year. (*e*) Second Year Scholarship of £20 tenable for one year. (*f*) Daniell Scholarship of £40 for one year. Awarded on University Honours Examination.

Fees.—Tuition fee of 35 guineas for the first year, £42 per annum for the second and third years, with a materials fee of 4 guineas in the first year, 6 guineas in the second year, 4 guineas in the third year. For prospectus and further information application should be made to the Dean of the Medical Faculty (Professor E. Barclay-Smith), King's College, Strand, W.C. 2.

Dental Course.—The College, in association with King's College Hospital, has instituted courses for the Degree in Dental Surgery of the University of London and for the Dental Diploma of the Conjoint Board.

Fees.—First year (Chemistry and Physics), 20 guineas; second and third years (Anatomy, Physiology, Dental Mechanics, and Dental Metallurgy), 52 guineas per annum. Fourth and fifth years (Hospital), 60 guineas per annum.

King's College Hospital Medical School.—The final subjects in the curriculum are taught at the Medical School of King's College Hospital, which is situated at Denmark Hill, S.E. 5. The hospital stands in the midst of a large South London population, from which an immense amount of clinical material is forthcoming. During the past year there were 216,483 attendances in the out-patient and casualty departments. Accommodation for 400 beds for in-patients has been built, and provision will ultimately be made for 600 beds. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physicotherapy, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry. The appointments open to students are those of clinical assistant to the special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers, house physicians and house surgeons; resident anæsthetist; resident radiologist; bacteriologist; clinical pathologist; pathological registrar; and medical, surgical, and obstetric registrarships. Sixteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Prizes.—(*a*) Warneford Scholarships, (*b*) Sambrooke Scholarship, (*c*) Rabbeth Scholarship, £20; (*d*) Medical Entrance Scholarships, £50 (Anatomy and Physiology), and £50 (Pathology and Pharmacology) open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (*e*) A Medical Entrance Scholarship in Science, value £50, tenable for five years, successful candidates to study at King's College and King's College Hospital. (*f*) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (*g*) Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital; (*h*) Carter Prize, £15, Botany; (*i*) Tanner Prize, £10, Obstetrics and Diseases of Women; (*j*) Todd Prize, £4 4s. and medal, Clinical Medicine; (*k*) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the nomination of the Regius Professors; (*l*) two Raymond Gooch Scholarships, £120 each, open to students of British Universities on certain conditions; (*m*) an Epsom College Scholarship, value £50, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London. The Warneford and Sambrooke Scholars are required to take the subjects of the preliminary and Intermediate examinations at King's College, and the final subjects at King's College Hospital.

Dental School.—When the Hospital was built accommodation was provided for a Dental Department. This Department fully equipped, is now in use, together with additional rooms for Dental Metallurgy, by the Dental School, which was opened in November, 1923, under the direction of Mr. A. Livingston, M.B., Ch.B., Mast. Dent. Surg. A full course is given in coöperation with King's College, and includes arrangements for students who desire to avail themselves of the special provisions of the Dentists Act.

Athletics.—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. An athletic ground, over six acres in extent, has been provided for the use of the students on Dog Kennel Hill, about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Platanes"—a hall of residence available for students belonging to the hospital.

Fees.—The composition fee for Hospital work and Final Medical subjects of the curriculum is 93 guineas if paid in one sum, or 95 guineas if paid in two instalments, in addition to the Entrance Fee of 10 guineas. The Calendar of the School will be sent on application to either of the following: Dr. H. Willoughby Lyle, *Dean*; Mr. S. C. Ranner, *Secretary of the Medical School*, King's College Hospital, Denmark Hill, S.E. 5.

London Hospital.—The hospital, with its Medical College and Dental School, is situated in Mile End-road. The hospital contains 950 beds of which number 849 are in constant use, and is the only general hospital for East London. During last year 18,237 in-patients and 132,023 out-patients received treatment, while 7991 major operations were performed. 41,831 out-patients attended the special departments for diseases of the Eye, Ear, Nose and Throat, Skin, Teeth, &c., and the Pediatric, Orthopædic, Venereal, Radiological, Electro- and Physico-Therapeutical and Inoculation Departments. The hospital presents, therefore, a large field for clinical instruction, and in its Wards and Out-patient Departments exceptional opportunities are afforded for acquiring an extensive and practical experience in all phases of disease.

A Clinical Unit in Medicine, under the charge of a whole-time director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and coordination of medical research.

also the Departments of Anatomy, Histology, Physiology, Biochemistry, and Pharmacology (the Intermediate Medical Sciences), and the Department of Hygiene and Public Health Research work is undertaken in all departments The completion of the Institute of Medical Sciences, which the generosity of the Rockefeller Foundation made possible, provides exceptional facilities for research and post-graduate study in anatomy, physiology, and pharmacology In particular might be specified the opportunities for investigation in human and comparative embryology and neurology, in histology, radiology, anthropology, biochemistry, and experimental physiology and experimental embryology Arrangements exist for the close correlation of work in the Institute with University College Hospital and Medical School

Faculty of Medical Sciences —Composition Fees —For the courses required by the University of London 1 For the First Medical Course, 35 guineas, entitling to one attendance and to the privileges of the Union Society for one session 2 For the Second Medical (Intermediate) Course 80 guineas, payable in two instalments of 40 guineas each This fee entitles to attendance at Anatomy and Physiology during three years and to one attendance at Organic and Applied Chemistry, and Pharmacology, and to the privileges of the Union Society or the Women's Union Society for two sessions

For the medical education required by the Examining Board in England (i) For the course for the Premedical Examination, 35 guineas, entitling to attendance and to the privileges of the Union Society for one session (ii) For the course for the First Examination, 80 guineas, payable in two instalments of 40 guineas each This fee entitles to attendance during three years (including one attendance at each Practical Course in Physiology) in all subjects except Practical Pharmacy It also entitles to the privileges of the Union Society for two sessions

Scholarships and Prizes —The first three items on the present list require a complete intermediate course at University College The money value and subjects at examinations are as follows (*a*) The Bucknill Scholarship, 160 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology , (*d*) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, Pharmacology, and Chemistry , (*e*) Schafer Prize in Physiology, £18 triennially , (*f*) Sharpey Physiological Scholarship, £200, Biological Sciences , (*g*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £16 a year , and (*h*) five Gold and five Silver Medals awarded annually in various departments

Women students are admitted

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL Dean Sir George Blacker Vice-Dean Mr Gwynne Williams Secretary Mr G E Adams Open to men and a limited number of women students Fees for Preliminary and Intermediate Course See under University College For the Final M B , B S (London) Course, 112 guineas if paid in one sum, 115 guineas if paid in two instalments, as follows—first year, 70 guineas , second year, 45 guineas This fee entitles to attendance on lectures and hospital Practice during three years and to one attendance on Practical Pathology *and Practical Surgery* Vaccination, Pharmacy and attendance at a Fever Hospital are not included This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, Durham, and other British Universities, and for the medical education required by the Examining Board in England and the Society of Apothecaries There are over 300 beds in the hospital

Clinical Units in Medicine and Surgery are now in operation The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Out-patient Department of the hospital A Unit in Obstetric Medicine has been established now that the new Obstetric Hospital is finished

The new buildings of the Obstetric Hospital of 60 beds (rendered possible by the Rockefeller Benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension to the Nurses' Home, and the new research laboratories for the Medical School, are now finished and in full occupation

Special Departments, Clinical and Laboratory Facilities —Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments tenable by Students —Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital Twelve house physicians, eight house surgeons, four senior and four junior obstetric assistants (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital Resident Medical Officer, Surgical Registrar, Medical Registrar, Obstetric Registrar, Harker-Smith Cancer Registrar, Ophthalmic Registrar, Casualty Medical Officer and a Casualty Surgical Officer, Assistants in Ear and Throat, Skin and Venereal Diseases Departments, and House Anæsthetist

Museum of Pathological Anatomy —The Museum is open for study from 9 A M to 5 P M Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of instruments formerly belonging to Robert Liston

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A M to 5 P M , Saturdays 9 A M to 1 P M It contains about 20,000 works on medical subjects, including all the current text-books and works of reference required for study or research

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members All male students of the Medical School are required to become members Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine *In its social* aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School The Athletic Ground, which is used in conjunction with the Union Society of the University of London, University College, is near the G.W.R Perivale station.

Scholarships, Prizes, &c—Two Entrance Scholarships, value £100 each, and two University Scholarships, value £90 and £60, are awarded annually in September The successful candidates are required to become general students of the school A Freer Lucas Scholarship is awarded annually on the nomination of the Headmaster of Epsom College There are also two Broderip Scholarships, value £60 and £40 respectively, the Lyell Gold Medal and Scholarship, value £55 5*s*, the John Murray Medal and Scholarship, value £25 (awarded every third year). the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas There are also numerous class prizes

Fees—The fees are arranged on a basis of an annual payment of approximately £45 for the six years of the curriculum. After six years, if the student is not qualified, the annual fee is £23

The Amalgamated Students' Club includes the following Medical Society, Common Room Society, Musical Society, cricket club, football clubs, athletic club, rowing club, chess club, lawn tennis club, and hockey club There are a restaurant and gymnasium in the school buildings, and large athletic grounds at Wembley, with new pavilion The subscription to the Amalgamated Students' Club is included in the above fees Full particulars on application to the Dean, Middlesex Hospital Medical School, W 1.

ST THOMAS'S HOSPITAL —This Hospital received its present charter from King Edward VI, but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 644 beds The in-patients last year numbered 10,777 whilst the number of attendances as out-patients, including the casualty and light departments, was 534,017 There are special departments for the treatment of women, children, diseases of the eye, ear, nose and throat, skin, teeth, and for orthopædics Nervous and mental diseases are treated in special departments An electro-cardiograph has been installed for the investigation of diseases of the heart The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction The Venereal Department has been established as part of the London County Council scheme Departments for Radiology, Electro-therapy, Phototherapy, Massage and Remedial Physical Exercises are also special features A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day, except Saturdays, at 2 P M Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions All appointments in the hospital are open to students without extra fee Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity Ward and district, thus obviating any necessity for seeking instruction elsewhere Students are instructed in the administration of anæsthetics by the hospital anæsthetists The Students' Club comprises a spacious restaurant and smoking and reading room A new Residential Club for Students, now being erected, will be opened early in 1927, and will provide resident quarters for some 60 students There is no occasion for students to leave the hospital buildings during working hours The curriculum is arranged to meet the requirements of all the Examining Bodies Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England Tutorial classes in all subjects precede the various examinations The hospital is easily accessible from all parts

Appointments Open to Students after Qualification—A Resident Assistant Physician and a Resident Assistant Surgeon at a salary of £225 each per annum, and a Resident Anæsthetist at a salary of £200 per annum are appointed annually Two Hospital Registrars, Medical and Surgical, at an annual salary of £250 each are appointed yearly The tenure of these offices may be renewed for a term not exceeding two years A Pathological Registrar to the Department of Obstetrics and Gynæcology (at an annual salary of £250), an Ophthalmic Registrar (at an annual salary of £50), and an Orthopædic Registrar (unpaid) are appointed yearly Two Senior Resident Casualty Officers (Medical and Surgical) are appointed yearly Eight Resident Casualty Officers and Anæsthetists are appointed every six months Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for re-election There are three Assistants in the Department of Pathology, the Senior receives £600 a year, and the two Juniors £450 each

Fees—The annual fees are For each year of study £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination Qualified practitioners are permitted to *attend the hospital practice on terms* which may be ascertained from the Medical Secretary

Scholarships and Prizes—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first year of study, two in Natural Science, of the value of £150 and £60 respectively, and the University Scholarship of £100 in any two of the following Anatomy, Physiology, Pathology, Chemistry The value of all entrance scholarships must be taken out in tuition fees *The money value and subjects of examination* of the remainder are as follows (*a*) William Tite Scholarship for second-year students, £25, (*b*) and (*c*) Musgrove Scholarship or (alternately) *Peacock* Scholarship, each *for third-year students and tenable* for two years, £35 each, (*d*) Mead Medal, Medicine, Pathology and Hygiene, (*e*) Wainwright Prize, Medicine, (*f*) Toller Prize, Medicine, (*g*) Cheselden *Medal*, *Surgery* and *Anatomy*, (*h*) *Clutton Memorial* Medal in Clinical Surgery, biennial; (*i*) Beaney Scholarship, £50, *biennially*, *Surgery and* Surgical Pathology, (*j*) Solly Medal and *Prize*, biennial, Reports of Cases, (*k*) Sutton Sams Prize, biennial, Report of Cases, (*l*) Bristowe Medal, *Pathology* and Morbid Anatomy, (*m*) *Hadden Prize*, *Pathology* and Morbid Anatomy, (*n*) *Grainger Testimonial Prize*, £31 10*s*, Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, Pathology, tenable for two years, £60 *annually*, (*p*) *School Council Research* Scholarship, £250 per annum, *tenable for two years*, (*q*) John and Temple Research Fellowship, tenable for two years, £450 *Children*

The Dean of the Medical School is Sir Cuthbert S Wallace, and the Medical Secretary Dr L B Maxwell, from whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE —University College has been constituted a University centre for the teaching of medical sciences The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences), Bursary tenable for two years for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st £20 (*k*) Helen Prideaux Prize and Julia Ann H Cock Prize awarded alternately every year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study £60 each (*l*) Dr Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June It is open to all medical women, preferably coming from India, or going to work in India for assistance in Post-graduate study (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year, next award in 1927 (*n*) Dr Margaret Todd Scholarship, tenable for four years, £37 10*s* a year, awarded in alternate years; next award in July, 1927 (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years awarded every four years, next award in July, 1928 (*p*) Alfred Langton Scholarships, tenable two years, one awarded annually, £50 a year (*q*) School Jubilee Bursary, tenable for three years, £50 a year (*r*) Flora Murray Bursary, awarded every year to a fifth-year student, £50 The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery Two Richardson-Kuhlmann Prizes are given each year, value £12 for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively Two Evans Prizes of £2 2*s* and £1 1*s* are given each year on the results of the class examination in Midwifery The Evans Prize for Operative Midwifery, value £5 5*s*, is awarded yearly The Edith Pechey Phipson Prize in Pharmacology, value £3 3*s*, is awarded annually

The Dean of the Medical School is Lady (Florence) Barrett C B E, M D, M S, the Honorary Secretary, Dr Janet Aitken, and the Warden and Secretary, Miss L M Brooks, to whom inquiries may be addressed

UNIVERSITY OF DURHAM

To return to the curriculums of the Universities, there are six English provincial universities providing a full course for the medical student

Nine degrees, two Diplomas, and one Licence are conferred—viz, the degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, Doctor of Hygiene, Bachelor of Dental Surgery, and Master of Dental Surgery the Diploma in Public Health, Diploma in Psychiatry, and the Licence in Dental Surgery

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations The subjects of the First Examination are—Elementary Biology and Organic Chemistry The subjects of the Second Examination are—Anatomy and Physiology The subjects for the Third Examination are—Materia Medica, Pharmacology, Therapeutics and Pharmacy, Medical Jurisprudence, Public Health, and Pathology and Bacteriology The subjects of the Fourth Examination are—Medicine, Clinical Medicine, Therapeutics, Surgery Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Psychological Medicine, and Diseases of the Skin, of the Throat Nose, and Ear, and of Children and Ophthalmology It is required that at least one of the five years of professional education shall be spent at the University College of Medicine, Newcastle-upon-Tyne

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice The candidate for the M D degree may present an essay or undergo a special clinical examination in the Theory and Practice of Medicine The subjects of examination for the M S are—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy Surgical Operations, Clinical Surgery

Doctor of Medicine (without residence)—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence Candidates must not be under 40 years of age and must have been in active practice for 15 years as registered medical practitioners They must also produce certificates of moral character from three registered members of the medical profession The fee is 50 guineas (including the degree fee), of which 20 guineas is retained if the candidate fails to satisfy the examiners

Doctor of Surgery—The University of Durham grants the Degree of Doctor of Surgery Candidates for this degree must be registered medical practitioners, and not less than 24 years of age They must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery and ancillary subjects One at least of the three years must be spent in the University The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology and Bacteriology, and the candidate must submit evidence of having so worked Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre Not less than six months of one of the three years must be spent in surgical study abroad The fee for the examination is £20, and the fee for the degree is £10

Candidates for any of the above degrees, diplomas, or licence, must give at least 28 days' notice to Professor Howden, Registrar, College of Medicine, Newcastle-upon-Tyne In the case of the M D. (essay) examination candidates must send in their essays before the 1st of April

Scholarships and Prizes—In connexion with this University the following Scholarships and prizes are awarded—University of Durham Entrance Scholarship, £25 a year for four years; Pears' Entrance Scholarship, £40 a year for three years (awarded every third year), Province of Durham Masonic (Entrance) Scholarship, £60; Heath Scholarship for Surgery, £200, available every second year

The following Scholarships are tenable for one year, namely—Tulloch Scholarship for Elementary Biology and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology, Gold Medal and £20, Charlton Scholarship for Medicine, £25, Gibb Scholarship for Pathology, £28; Luke Armstrong Scholarship for Comparative Pathology, £25 Stephen Scott Scholarship for Surgery, £40, Philipson Scholarships for highest marks in Final M B, B S Examinations, two of £48 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £325, Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy, and Outterson Wood Prize for Psychological Medicine, £10. Sewell Memorial Prize and Silver Medal for Clinical Pathology. At the end of each session a Prize of Books is awarded in each of the regular classes For further information apply to Professor R Howden Registrar of the College

College of Medicine, Newcastle-upon-Tyne—Clinical instruction is given at the Royal Victoria Infirmary, containing about 550 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work Students do midwifery at the Princess Mary Maternity Hospital

Scholarships and Prizes—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School, the second two (*c*) and (*d*) entitle to a final course at the Medical School The money value and subjects of examination are as follows —(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology, (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions 112 guineas each, Anatomy or Physiology, or General Pathology, (*e*) Graham Scholarship in Pathology £300 per annum for two years, awarded by the Senate of the University of London, (*f*) Atkinson Morley Scholarship, tenable for three years £45 per annum, Surgery, (*g*) Atchison Scholarship, tenable for two years, £55 per annum General Proficiency in Medical Studies, (*h*) Magrath Clinical Scholarship about £150, Clinical Cases. (*i*) Percival Alleyn Scholarship about £75, Surgery, (*j*) Filliter Exhibition, £30, Pathology, (*k*) Erichsen Prize, £10 10s, Practical Surgery, (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine, (*m*) two Liston Gold Medals for Clinical Surgery, (*n*) Alexander Bruce Gold Medal for Pathology and Surgery, and (*o*) Tuke Silver and Bronze Medals for Pathology (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology (*q*) Leslie Pearce Gould Travelling Scholarship for Surgery

Residence of Students—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers

---

WESTMINSTER HOSPITAL—The hospital contains 236 beds and affords relief to upwards of 3500 in-patients and 25,000 out-patients annually There are separate departments for Diseases of the Eye, Skin, Teeth, Ear, Nose, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, for Venereal Diseases, and for Massage, Electrical and Light Treatment The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school

The usual registrarships and house appointments are open to male and female students.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore

Scholarships and Prizes—The following Entrance Scholarships are offered for competition: Winter Session Two Scholarships in Anatomy and Physiology, £70 each Summer Session · Two Scholarships in Anatomy and Physiology, £70 each A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for · Sturges Prize in Clinical Medicine, about £6, Reports on Cases, Clinical Surgery Prize, £5, Reports on Cases, Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology, Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15, Jelf Medal awarded to Third-year Students, Second year Scholarship £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry, Daniell Scholarship, tenable for two years, £20, Chemistry, Rabbeth Scholarship, open to First-year Students, £20, Class Examinations in the Preliminary Scientific Course, and the Sambrooke King's College Scholarship in Science, value £25 Inquiries may be addressed to the Dean, Dr A S. Woodwark

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick square, W.C—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £240 in five instalments This sum includes library and laboratory fees Arrangements are made for pre-medical courses in Chemistry and Physics, which are included in these fees

The Royal Free Hospital contains 240 beds The Hospital also has large Casualty and Out-patient Departments, and Departments for Special Diseases A new and specially equipped block contains the Obstetrical and Gynæcological Unit, which controls 68 beds A Children's Ward of 16 beds and a Light Department have recently been added to the Hospital Maternity Districts are attached to the Unit operating in the Gray's Inn-road and Essex road areas A new Maternity Hostel has been acquired at 434, Essex-road Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, South London Hospital, and Royal London Ophthalmic Hospital

Courses are arranged for the Primary Fellowship Examination of the College of Surgeons, also for dental students in conjunction with the Royal London Dental Hospital, Leicester-square.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, 5, Mecklenburgh-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies The School sports ground, consisting of 6½ acres of freehold land, is situated at Sudbury (easily reached from Euston Station), and provides facilities for tennis, hockey, lacrosse, and cricket

Scholarships and Prizes—(*a*) Isabel Thorne Scholarship, £30 (*b*) St Dunstan's Medical Exhibition, £60 a year, tenable for three or five years (*c*) Mrs George M Smith Scholarship, £50 a year, tenable for three or five years, and next to be awarded in 1927. (*d*) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1927, £90 (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year (*f*) Sir Owen Roberts Scholarship, £75 a year for four years (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years, next award in July, 1930, £10 (*i*) John Byron

Fees—Matriculation, £2; First Examination, Part I, £2 10s.; First Examination, Part II, £2 10s; Second Examination, £2 10s; Third Examination, £2 10s, Final Examination, £10; M D. or Ch M, £12 10s

At the University of Birmingham the following Scholarships are awarded.—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B, Ch B candidates, tenable at some University or Hospital not in Great Britain or Ireland (available for year 1926–27); (*b*) two Ingleby Scholarships of £10 each awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*e*) Dental Scholarship of £37 10s, Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10s. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate passing the Final M B, Ch.B. in June, who obtains the highest marks in Clinical Medicine, provided the marks so gained be not less than 60 per cent The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in fourth and fifth years (open to all students)

The Sampson Gamgee Memorial Medal for Surgery (Gold Medal) is awarded annually to candidate passing Final M.B, Ch B Examination in June for best Examination in Surgery provided that not less than 60 per cent of marks is obtained (paper, oral, and clinical)

Post-graduate Courses—A "William Withering Lectureship' has been established, and this takes the place of the Lectureship in Morbid Psychology in and after 1927 A course (or courses) of lectures will be given annually for post-graduates on subjects to be chosen from year to year In 1927 a course of lectures on Heredity will be given by Dr F. A. E Crew, of Edinburgh. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers Post-graduate Courses of Clinical Demonstrations (for General Practitioners) at the Birmingham General Queen s, and Children's Hospitals are arranged annually (April to July).

Clinical Instruction—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board Appointments are open to students varying from £40 to £200 a year.

BIRMINGHAM GENERAL HOSPITAL—370 beds are in daily use, 6500 in-patients per annum. Special wards for Children, Gynæcological Ear and Throat, Venereal, Maternity, and Septic cases; special beds for Eye and Skin cases About 50,000 out-patients per annum Laboratories for Bacteriology and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students Clinical instruction in all the special departments, which include those for Radium. Electrotherapy, Electrocardiographic investigation, and Venereal Diseases Post-graduate classes in every branch of medicine and surgery. The Jaffray Branch Hospital contains 56 beds

QUEEN'S HOSPITAL (Beds 224)—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons There are also special departments for gynæcology and ophthalmology. dentistry, radiography, pathology, bacteriology, biochemistry, massage, electricity, whirlpool baths, electrocardiograph, &c

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of over 250. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations Post-graduate courses are available on various subjects when a sufficient number of graduates are present. A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

UNIVERSITY OF LIVERPOOL

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M B. and Ch.B), Doctor of Medicine (M D), Doctor in Philosophy (Ph D.), Master of Surgery (Ch M), Master of Hygiene (M H), and Master of Orthopædic Surgery (M Ch Orth)

Degrees of Bachelor of Medicine and Bachelor of Surgery—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination, The fee is £5 for each examination The subjects of the First Examination are: (1) Chemistry; (2) Physics; (3) Biology (Zoology and Botany) The subjects of the *Second Examination* are (*a*) (1) Anatomy; (2) Physiology (including Physiological Chemistry and Histology); and (*b*) (3) Elementary Bacteriology, (4) Clinical Chemistry, (5) General Pathology Candidates may present themselves in (*a*) or (*b*) separately The subjects for the Final Examination are: (*a*) (1) Special Pathology and Morbid Anatomy; (2) Forensic Medicine and Toxicology; (3) Public Health: (4) Pharmacology and General Therapeutics (*b*) (5) Obstetrics and Diseases of Women, (6) Surgery, Systematic, Clinical, Operative and Practical, including Ophthalmology;

Post-graduate Instruction —A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College, the Royal Victoria Infirmary and other associated hospitals, and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer session as well as an intensive course in the summer vacation

The Bacteriological Laboratory —The Bacteriological Laboratory is adjacent to Armstrong College

Students' Union Buildings have been erected and furnished at a cost of over £40,000, and are now in daily use

Princess Mary Maternity Hospital — The new Maternity Hospital was opened by H R H Princess Mary Viscountess Lascelles in November, 1923 The hospital is thoroughly up to date, excellently equipped, contains 90 beds, and there is an annual indoor and outdoor attendance of 3000 cases

---

Newcastle-upon-Tyne Royal Victoria Infirmary —The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII in 1906 The number of beds is 572. The number of in-patients annually is 12,000 and out-patients' attendances 297,000. The medical students of the University of Durham attend the practice of this hospital Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians and Assistant Surgeons, and demonstrations are given in the several out-patient departments daily Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students Ophthalmic, Throat, Nose, and Ear, Skin, Gynæcological, and Electrical The hospital building contains the following laboratories: 1 Special Pathological Laboratory, attached to the post-mortem rooms 2 Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c 3 There is in addition a Clinical Laboratory attached to each ward and to the out-patient department There are five operating theatres in use in the hospital The winter session of 1926 opens on Oct 4th and the summer session of 1927 on April 12th

Applications for detailed information should be made to the Dean, Dr Horsley Drummond, at the hospital

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction Practical Midwifery can be studied at the Princess Mary Maternity Hospital Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health Ophthalmology is taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye

Post-Graduate Instruction —For the year 1926–1927 the following post-graduate courses have been arranged:—1 General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks One course will be held from October to December and one from April to June 2 Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects Gynæcology; Diseases of the Eye, Diseases of the Throat, Nose and Ear, Diseases of the Skin, Venereal Diseases, Neurology; Diseases of Children, Special courses in Midwifery will be held at the Princess Mary Maternity Hospital 3 An intensive course of 14 days' duration in the early part of the Summer Vacation, 1927 4 In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary for specified periods

---

UNIVERSITY OF BIRMINGHAM

The University of Birmingham grants the degrees of M B, Ch B, M D, Ch M, and Ph D (for Research Study), and also a degree and a diploma in Public Health The course for the Bachelors' degrees extends over five years from the date of commencement of professional study As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Biology and Organic Chemistry In the case of such students at least three years must be spent in attendance upon classes at the University The fifth year may be spent at any other medical school recognised by the University

Degrees of Bachelor of Medicine and Bachelor of Surgery —The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof, and a recognised Pre Medical Examination in Chemistry and Physics All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester First Examination —Part I, Elementary Biology and Organic Chemistry, Part II, Anatomy and Physiology Second Examination —General Pathology and Bacteriology, Materia Medica, and Pharmacy Third Examinations (at the end of the fourth year)—Forensic Medicine, Toxicology, Public Health, and Therapeutics Two years' hospital work must have been accomplished Final Examination —Medicine Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months and Vaccination instruction must be taken out and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery

Degrees of Doctor of Medicine and Master of Surgery At the end of one year from the date of having passed the final M B, Ch B examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M D, and one in Principles and Practice of Surgery, including operations on the cadaver, for the Ch M A thesis of exceptional merit may exempt from any part of these examinations

Degree of Ph D —The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and to submit themselves for oral and possibly written examination

Fees—Matriculation, £2; First Examination, Part I, £2 10s.; First Examination, Part II, £2 10s; Second Examination, £2 10s; Third Examination, £2 10s, Final Examination, £10; M D or Ch M, £12 10s

At the University of Birmingham the following Scholarships are awarded.—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B, Ch B candidates, tenable at some University or Hospital not in Great Britain or Ireland (available for year 1926–27); (*b*) two Ingleby Scholarships of £10 each awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners, (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board, (*e*) Dental Scholarship of £37 10s, Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10s. each In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate passing the Final M.B, Ch.B. in June, who obtains the highest marks in Clinical Medicine, provided the marks so gained be not less than 60 per cent The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in fourth and fifth years (open to all students)

The Sampson Gamgee Memorial Medal for Surgery (Gold Medal) is awarded annually to candidate passing Final M.B, Ch B Examination in June for best Examination in Surgery provided that not less than 60 per cent of marks is obtained (paper, oral, and clinical)

Post-graduate Courses—A "William Withering Lectureship" has been established, and this takes the place of the Lectureship in Morbid Psychology in and after 1927. A course (or courses) of lectures will be given annually for post-graduates on subjects to be chosen from year to year In 1927 a course of lectures on Heredity will be given by Dr F A E Crew, of Edinburgh The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers Post-graduate Courses of Clinical Demonstrations (for General Practitioners) at the Birmingham General Queen's and Children's Hospitals are arranged annually (April to July)

Clinical Instruction—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board Appointments are open to students varying from £40 to £200 a year

BIRMINGHAM GENERAL HOSPITAL—370 beds are in daily use 6500 in-patients per annum Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, and Septic cases. special beds for Eye and Skin cases About 50,000 out-patients per annum Laboratories for Bacteriology and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electrotherapy, Electrocardiographic investigation and Venereal Diseases Post-graduate classes in every branch of medicine and surgery The Jaffray Branch Hospital contains 56 beds

QUEEN'S HOSPITAL (Beds 224)—Similar arrangements for clinical teaching are made here, and the material also is excellent Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons There are also special departments for gynæcology and ophthalmology, dentistry, radiography, pathology, bacteriology, biochemistry, massage, electricity, whirlpool baths, electrocardiograph, &c

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of over 250. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations Post-graduate courses are available on various subjects when a sufficient number of graduates are present A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B and Ch.B), Doctor of Medicine (M.D), Doctor in Philosophy (Ph D.), Master of Surgery (Ch M), Master of Hygiene (M H), and Master of Orthopædic Surgery (M Ch Orth).

Degrees of Bachelor of Medicine and Bachelor of Surgery—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination The other three years may be passed at any college or medical school recognised for this purpose by the University. UNIVERSITY OF BIRMINGHAM

The University of Birmingham grants the degrees of M B, Ch B, M D, Ch M, and Ph D (for Research Study), and also a degree and a diploma in Public Health The course for the Bachelors' degrees extends over five years from the date of commencement of professional study As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Biology and Organic Chemistry In the case of such students at least three years must be spent in attendance upon classes at the University The fifth year may be spent at any other medical school recognised by the University

Degrees of Bachelor of Medicine and Bachelor of Surgery—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof, and a recognised Pre-Medical Examination in Chemistry and Physics All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester First Examination—Part I., Elementary Biology and Organic Chemistry, Part II, Anatomy and Physiology Second Examination—General Pathology and Bacteriology, Materia Medica, and Pharmacy Third Examinations (at the end of the fourth year)—Forensic Medicine, Toxicology, Public Health, and Therapeutics Two years' hospital work must have been accomplished Final Examination—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months Vaccination instruction must be taken out and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat Medical and Surgical Anatomy, and Operative Surgery

Degrees of Doctor of Medicine and Master of Surgery At the end of one year from the date of having passed the final M B, Ch B examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M D, and one in Principles and Practice of Surgery, including operations on the cadaver, for the Ch M A thesis of exceptional merit may exempt from any part of these examinations

Degree of Ph D—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, *Colonial, or* other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and to submit themselves for oral and possibly written examination an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.)

Degrees of B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in Medicine who in their third year of study for the degree of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in Anatomy or Physiology who are students in Medicine are required to attend courses in advanced Anatomy and Physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science may proceed to the degree of M.Sc. by presentation of an approved thesis.

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at the Victoria University:—Scholarships: Dreschfeld Entrance (triennial), £20; John Russell Medical Entrance, £45; Sam Gamble Entrance for Women: Graduate Entrance (fees up to 160 guineas): two Dauntesey Medical Junior, £50 each; Dauntesey Medical Senior £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology: Platt Physiological, £90; Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100. Fellowships: Leech Research £70; Professor Tom Jones Surgical, £105; Morrison Watson in Anatomy, £150; Delepine in Preventive Medicine (biennial), £300; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology £15; Turner Medical £20; John Henry Agnew in Diseases of Children, £30; Dumville Surgical £15; Knight Prize in Psychological Medicine, £50; Graduate Prizes £5 each. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Clinical Instruction.—MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 668 patients (including 54 beds at the Central Branch). The medical side consists of five units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing and apparatus rooms, and its own class-room attached. All of these units are occupied. In the educational block is a large lecture theatre and a museum. In the same building is housed the X ray department, which has nine separate X ray outfits for different purposes, and in which one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with this department.

The number of patients treated during the year 1925 was 11,047 in-patients and 45,062 out-patients; of the latter figure 10,810 were treated in the accident room of the Infirmary. Over 9000 operations are performed annually in the operation theatres.

Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 132 beds; (2) the Royal Lunatic Hospital at Cheadle accommodating with its branches 430 patients; and (3) the Central Branch in the City, which has now accommodation for 54 patients. The Associated Hospitals thus contain 1230 beds and are under the same management. Women students are admitted on the same terms as men.

Fees.—Medical Practice: Three months, 7½ guineas; six months, 12 guineas; twelve months, 18 guineas; full period required by the Examining Bodies, 60 guineas.

Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

Post-Graduate Courses.—Post-graduate Lectures open to all medical men and women are given by members of the staff and others from the last week in September until Christmas, and from the beginning of March until Whit-week. These take place at 4.15 P.M. on Tuesdays and Fridays and are free. Information can be obtained from the Secretary of the Post-Graduate Committee, Royal Infirmary, Manchester.

The Dean of Clinical Instruction is Dr. T. H. Oliver.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and Lytham St. Anne's.—The hospital contains 190 beds and 30 in the Convalescent Home, Lytham St. Anne's. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electro-therapeutic Department. Four Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is an Orthopædic Department. Out-patients day is on Tuesday at Gartside-street.

(7) Medicine, Systematic and Clinical, including Therapeutics, Mental Diseases, and Diseases of Children Candidates may present themselves in Parts (*a*) and (*b*) separately, but candidates must have completed the fifth year of medical study before taking Part (*b*)

Degrees of Doctor of Medicine and Master of Surgery No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least two years have elapsed since he passed the examinations for those degrees, or, in the case of the degree of Doctor, unless, having obtained substantially equivalent degrees in an approved University, he has subsequently spent two years in the University or in the Clinical School in the performance of research or the conduct of systematic clinical observations Candidates for the degree of Doctor of Medicine are required to present a thesis together with, if desired, published original work relative to medical science An examination is required if the work submitted is not of special merit If the work submitted is of special merit, but extremely specialised, a candidate may be asked to submit a reasoned report on a subject set by the examiners

The University also awards a Diploma in Medical Radiology and Electrology—Part I, Physics, Part II, Radiology and Electrology The parts may be taken at one examination or separately

At this University the following Scholarships and Fellowships and Prizes are awarded —(*a*) Robert Gee Entrance Scholarship (Men) annually of £40, tenable for four years; (*b*) Lyon Jones Scholarship, No 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M B Subjects, (*c*) Lyon Jones Scholarship, No 2 of £21, Compétitive Examination on results of Professional Examination in Anatomy, Physiology Elementary Bacteriology, Clinical Chemistry, and General Pathology, (*d*) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects and (*e*) Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students, (*f*) University Scholarship of £50 for one year, awarded on results of the Final (Part A) Examination for the degrees, (*g*) Holt Fellowships Physiology and Pathology, of £150 each for one year, (*h*) Gee Fellowship, Anatomy of £100, for one year, (*i*) John Rankin Fellowships in Anatomy two, each of the value of £120, tenable for two years, (*j*) Johnston Colonial Fellowship Bio-Chemistry, of £100 for one year (*k*) John W Garrett International Fellowship, Bacteriology of £100, for one year, (*l*) Thelwall Thomas Fellowship Surgical Pathology, of £150 for one year, (*m*) Ethel Boyce Fellowship in Gynæcological Pathology of £100 for one year (*n*) Mary Birrell Davies Memorial Fund Scholarship of the value of £60, tenable for four years offered for competition in alternate years open only to women students who will have attained the age of 19 on the first day of October next following the award, (*o*) Rankin Exhibition in Practical Anatomy, of £25 for one year, (*p*) Lady Jones Research Fellowship in Orthopædic Surgery £200 (*q*) Samuels Memorial Scholarships, three at £20, numerous prizes and medals

Medical School Buildings—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation All the laboratories and class-rooms are situated close together, communicating with one another and are made up of four large blocks of buildings which form one side of the College quadrangle There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy Surgery, Toxicology, and Ophthalmology and the Thompson-Yates Laboratories for Physiology and Pathology A new building for Tropical Medicine has been opened

Clinical Instruction—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL and the STANLEY HOSPITAL and of six special hospitals—the Eye and Ear Infirmary, the Hospital for Women (with the Samaritan Hospital), Liverpool Maternity Hospital the Royal Liverpool Children's Hospital, St Paul's Eye Hospital, and St George's Hospital for Skin Diseases These hospitals contain in all a total of about 1445 beds The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom All the hospitals are within easy access of the University There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school

Public Health Department—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool

---

VICTORIA UNIVERSITY OF MANCHESTER

Four degrees in Medicine and Surgery are conferred by the University—viz, Bachelor of Medicine and Bachelor of Surgery (M B and Ch B), Doctor of Medicine (M D), and Master of Surgery (Ch M) A Diploma in Psychological Medicine, a Diploma in Public Health, and a Diploma in Bacteriology are awarded by examination to registered medical practitioners

Degrees of Bachelor of Medicine and Bachelor of Surgery—Before admission to the degree of M B or Ch B candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M B Examination

The First Examination—(1) Chemistry and Physics, (2) Biology Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects The Examination is divided into two parts Part 1, Inorganic and Elementary Organic Chemistry and Physics Part 2, Biology The candidates sit for these parts separately

The Second Examination—(1) Anatomy and Histology, (2) Physiology, including Physiological Chemistry

The Third Examination—(1) Pharmacology and Therapeutics, (2) Pathology

The Final Examination—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children) (2) Surgery, Systematic, Clinical, and Practical, (3) Obstetrics and Gynæcology (including Clinical and Practical), (4) Forensic Medicine (including an Oral Examination), (5) Hygiene and Preventive Medicine The Final Examination is divided into two parts Candidates for the Second Part must complete the sixth year of medical study

Degree of Doctor of Medicine—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees Candidates may elect either (1) to present an original dissertation, or (2) to undergo

Scholarships, &c—At this University, in addition to six Edgar Allen scholarships of £125 a year for three years, holders of which can take the courses in the Faculty of Medicine, there are 11 scholarships tenable in the Faculty of Medicine Full particulars as to curriculum, scholarships &c may be had on application to the Registrar or to the Dean of the Medical Faculty.

The Medical School—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical Department occupies the entire north wing of the University quadrangle The various athletic and other students' societies are under the management of the Union Representative Council, elected annually There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c, at extremely moderate prices The University journal, *Floreamus*, edited by a committee of staff and students, is published each term The University Halls "Oakholme," Clarkehouse-road, "Tapton Cliffe," Fulwood-road and "Endcliffe House," Endcliffe Vale-road, are recognised by the Senate as halls of residence for women students, full particulars may be obtained from the tutor for women students Stephenson Hall is a hall of residence for men students, particulars may be obtained from the Warden

Clinical Instruction—The University is within easy reach of the various hospitals with which it is connected for clinical purposes These are as follows: The ROYAL INFIRMARY (Secretary, Mr. J. W. Barnes), containing 502 beds, with an annual average number of over 5400 in-patients, over 23,000 out-patients, and over 22,000 casualties, the Royal Hospital (Sec, Mr W H Booth), with 316 beds, and an annual number of 4000 in-patients, over 84,000 out-patients and over 21,000 casualties, and the Jessop Hospital for Diseases of Women, with 93 beds, over 1000 in-patients, and over 2700 out-patients, also a Maternity department, with about 900 in-patients per annum and about 250 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (690 beds) and on Mental Diseases at the South Yorkshire Mental Hospital (1740 beds) For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 818 beds for the treatment of medical, surgical, and special cases There are special departments for the treatment of Diseases of the Eye at each institution, with wards assigned to them In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases Instruction is also given at the South Yorkshire Mental Hospital (1740 beds) Every facility is afforded in the various laboratories for the prosecution of advanced studies and research

Fees—The Medical Composition Fee is £38 a year for each of the five years

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees—Bachelor of Medicine and Bachelor of Surgery (M B and Ch B), Doctor of Medicine (M D), Master of Surgery (Ch M), Bachelor of Dental Surgery (B D S), and Master of Dental Surgery (M D S) There are also the following diplomas: Diploma in Public Health (D P H), Diploma in Dental Surgery (L D S) and Diploma in Veterinary State Medicine

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate All courses, degrees, and diplomas are open to men and women alike

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics, of which three shall have been passed in the University, and two of these three subsequent to passing the second examination All candidates for the degrees of M.B, Ch B, are required to satisfy the examiners in the several subjects of three examinations

The First Examination—The subjects of examination are. Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B Sc curriculum This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I) and Advanced Anatomy and Physiology (Part II) Parts I and II may be passed separately or together.

The Final Examination.—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II) The subjects included in Part II may be taken in two groups—viz, Group I, Surgery and Obstetrics, Group II, Medicine, Public Health, Special Pathology, Forensic Medicine, and Toxicology Candidates may pass Parts I and II together, or separately, and the two groups of Part II may be taken together or separately Forensic Medicine and Toxicology may be taken with Part I, or with Group II of Part II

Degree of Doctor of Medicine—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof

Degree of Master of Surgery—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery. The degree may be taken also in General Surgery, and a Special Subject—e g, Oto-Rhino-Laryngology, Ophthalmology, and Gynæcology.

Clinical Instruction—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects Departments are provided and well equipped for X ray work, both for diagnosis and a ward at Pendlebury is devoted to cases needing operative treatment Out-patients are seen daily at 6 A M at the Out-patient Department, Gartside-street, Manchester Secretary Mr W M Humphry

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road, Manchester —The hospital contains 72 beds. Out-patients are seen daily from 8 30 to 12 A M

UNIVERSITY OF LEEDS

Four degrees in Medicine and Surgery are conferred—viz . Bachelor of Medicine and Bachelor of Surgery (M B and Ch B), Doctor of Medicine (M D), Master of Surgery (Ch M), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine

Degrees of Bachelor of Medicine and Bachelor of Surgery —Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination Candidates must also satisfy the examiners in the several subjects of the following examinations entitled respectively the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead , the First Examination , the Second Examination , and the Final Examination

The *First Examination* —The First Examination consists of Part I , Physics and Chemistry ; Part II , Zoology and Botany Candidates will be allowed to pass the two parts separately

The *Second Examination* —The Second Examination consists of Part I , Organic Chemistry , Part II , Materia Medica, Practical Pharmacy, and Pharmacology , Part III , Anatomy and Physiology Candidates will be allowed to pass any parts separately, but Part I must be passed before Parts II or III

The *Final Examination* —The Final Examination consists of Part I , Pathology and Bacteriology , Part II , Medicine, Surgery, Obstetrics, Gynæcology, and Clinical Pathology , Part III , Forensic Medicine, Public Health, and Therapeutics Part I may be taken at the end of the second clinical year, and Parts II and III may be taken at the end of the third clinical year but not before the completion of the fifth year of medical study If taken separately Part II must be passed before Part III

Degree of Doctor of Medicine —Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least one year has elapsed since they passed the examination for those degrees Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, may be required to pass an examination

The first term commences on Oct 1st. Prospectus can be obtained from the Academic Sub-Dean

Post-graduate work —Practitioners wishing to attend Infirmary practice during short periods, or post-graduate classes held by members of the clinical staff, may do so on application to the Clinical Sub-Dean, from whom particulars may be obtained

Clinical Instruction.—The Leeds General Infirmary, in connexion with this medical faculty, has accommodation for 630 in-patients, including 88 beds at branch hospitals in the country During 1925 12,598 in-patients and 53,529 new out-patients were treated Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children Several valuable prizes are given at the end of each session Numerous appointments at the Infirmary are annually open to students after qualification Further particulars may be obtained from the General Manager

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W R) Mental Hospital and Leeds City Fever Hospital respectively

UNIVERSITY OF SHEFFIELD

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M B , Ch B), Doctor of Medicine (M D.), and Master of Surgery (Ch M), Bachelor of Dental Surgery (B D S), and Master of Dental Surgery (M D S) There is also a Diploma of Licentiate in Dental Surgery The courses and degrees in the Faculty of Medicine are open to men and women alike Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics

Degrees of Bachelor of Medicine and Bachelor of Surgery —A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination

The First Examination —The subjects of the examination are Chemistry, Physics, and Biology The Intermediate B Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each

The Second Examination —The subjects are Anatomy and Physiology Candidates must have completed the second year of professional study

The Third Examination —The subjects are Pathology, Pharmacology, Anatomy, and Physiology Candidates must have completed the Lent Term of the fourth year of professional study

The Final Examination —The subjects of the examination are —Part I —Forensic Medicine and Public Health , Part II —Medicine (including Mental Diseases and Diseases of Children), Surgery, Obstetrics (including Gynæcology) Candidates for Part I must have completed the Michaelmas Term of the fifth year of professional study ; candidates for Part II must have completed the fifth year of professional study.

Degree of Doctor of Medicine —Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M B , Ch.B at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery —Candidates must have taken the M B , Ch B at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology

Diplomas are registrable on the Medical Register, the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board, the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers These courses may be commenced or attended before the required Preliminary Examination in General Education is passed The examination is partly written, partly oral and partly practical A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months and he must produce evidence of further instruction in the subject or subjects of failure The fee for the examination is £3 3*s*, for re-examination in Chemistry £2 2*s*, and for re-examination in Physics £1 1*s*

There are two Professional examinations called the *First* and *Final Examination* The courses of study for these examinations may be commenced before the Pre-Medical examination in Chemistry and Physics or some equivalent examination has been passed, provided that three terms of study are completed after the examination has been passed

The subjects of the First Professional Examination are Section I (*a*) Anatomy, including Histology and Embryology (*b*) Physiology, including Bio-Chemistry Section II Pharmacology, Practical Pharmacy and Materia Medica A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Bio-Chemistry and Bio-Physics during five terms, courses of instruction in Pharmacology, Practical Pharmacy and Materia Medica A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part

Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination The fee for the First Professional Examination is £10 10*s*, for re-examination after rejection in Section I £6 6*s*, for re-examination after rejection in either part of Section I £3 3*s*, for re-examination after rejection in Section II £3 3*s* A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects

Final Professional Examination—The subjects of the Final Professional Examination are Section I (*a*) Pathology, including Morbid Anatomy, Morbid Histology and Clinical Pathology (*b*) Bacteriology Section II Part I Medicine, including Medical Anatomy, Forensic Medicine and Public Health Part II Surgery, including Surgical Anatomy and the use of Surgical Appliances Part III Midwifery and Gynæcology The examination is partly written, partly practical, partly clinical and partly oral A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately or may take the whole examination together He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from Section I The fee for admission to Section I is £4 4*s*; for admission to Section II, Part I, £10 10*s*, Part II, £10 10*s*, Part III £6 6*s*, and the re-examination fees are respectively £3 3*s*, £6 6*s* £6 6*s*, and £4 4*s*.

Students of recognised universities in England, Scotland and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First Examination of the Examining Board, may enter for a part of the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates but they must complete 33 months of clinical study before completing the examination

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board under the old Regulations, or of the First Examination and Section I of the Final Examination under the new Regulations may present themselves for the Final Examination under special conditions The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, and in Laryngology and Otology Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University Particulars and conditions of admission to all examinations, fees, &c, may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W C 1

ROYAL COLLEGE OF PHYSICIANS OF LONDON·

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination

Membership—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years The alteration in the by-law of the College is designed to enable men who have just finished house appointments to sit for an examination for which their recent clinical experience has exactly fitted them The candidate must either have passed the examinations for the licence of the College, or else be a registered medical practitioner who has obtained the degree of Doctor or Bachelor of Medicine at a University recognised by the Censors Board The examination is directed partly to pathology and partly to the practice of medicine Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German Further information may be obtained from the Registrar at the College The fee for admission as a Member of the College is 40 guineas, except when the candidate for membership is a licentiate of the College, in which case the fee already paid for the licence is deducted from the 40 guineas The fee for the examination is 6 guineas, which is reckoned as part of the fee for admission in the case of success

Fellowship—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds The total number of beds available for clinical instruction is therefore about 750

Appointments —(1) Undergraduate Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological and ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital In these institutions the dressers reside in rotation free of charge (2) Post-graduate At the Bristol Royal Infirmary Four house surgeons, £80 each per annum , two house physicians, £80 , two resident obstetric officers, one of whom is also ophthalmic house surgeon, £100 and £80 ; ear, nose, and throat house surgeon. £80 , dental house surgeon, £80 All these appointments are made for six months From the resident officers a senior resident officer is appointed at a salary of £200 At the Bristol General Hospital Senior resident medical officer, £250 per annum , casualty house surgeon, £80 per annum ; two house physicians, £80 per annum , house surgeon, £80 per annum , special obstetric physician, £80 per annum , house surgeon to special departments, £80 per annum , dental house surgeon, £300 per annum Appointments are for six months, except that of senior resident medical officer, which is for two years

Scholarships —The following are among the scholarships and other awards open to students of the school The Ashworth Hallett Scholarship, value £45, open to women only , two Martin Memorial Pathological Scholarships of £10 each , the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery , the Committee's Gold and Silver Medals for fifth-year students for general proficiency ; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy , the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology , the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery ; the Suple Surgical Prize, a gold medal and 7 guineas , the Suple Medical Prize a gold medal and 7 guineas , the Henry Marshall Prize, value £12, for dressers; the H M Clarke Scholarship, value £15, for proficiency in surgery , the Sanders Scholarship, value £22 10*s* , for general proficiency, the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose and throat, value £14 ; Lady Haberfield Scholarship, value about 25 guineas ; Phyllis Siepman Prize, for proficiency in Diseases of Children, value £25

Bristol City Senior Scholarships and those offered by the counties of Gloucestershire, Somerset, Wilts, and Devon, are tenable in the University

Some of the Fellowships awarded by the Colston Research Society for research in the University are allotted to the Faculty of Medicine
